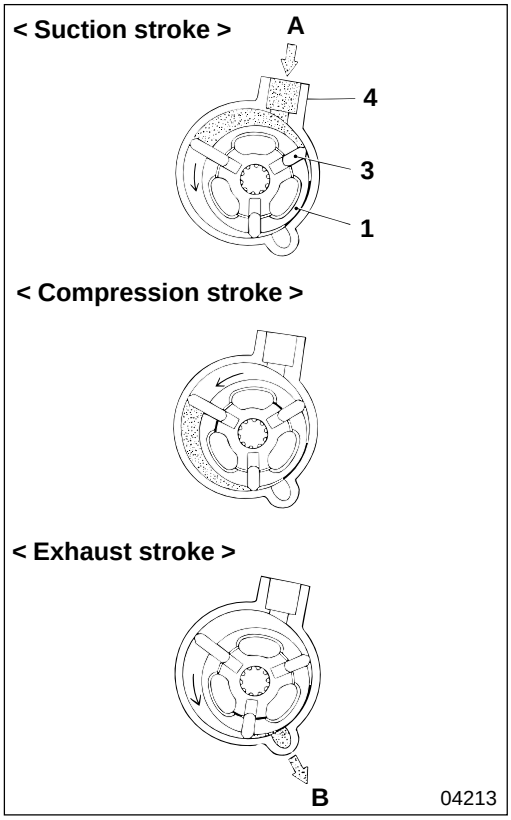
- The vacuum pump is installed on the rear part of alternator and is rotated by the V-belt.
- Check valve **2** is fitted to prevent the atmospheric pressure and the lubricating oil from flowing in reverse from the vacuum pump when the engine is stopped.



● **Operation**

- Inside cylindrical housing **4**, rotor **1** equipped with three vanes (movable blades) **3** rotates, pressing the vanes against the inside surface of the housing by centrifugal force.
- Since rotor **1** is eccentric with respect to housing **4**, as the rotor rotates, the atmospheric pressure of the exhaust brake unit is drawn in from inlet **A** and discharges from outlet **B** by the gradual compression of the air. This repetition of the suction, compression and exhaust strokes generates a vacuum, realizing a near-vacuum in the exhaust brake unit.
- The engine oil that lubricates and cools the inside of housing **4** is returned, along with air pressure, through outlet **B** to the oil pan.

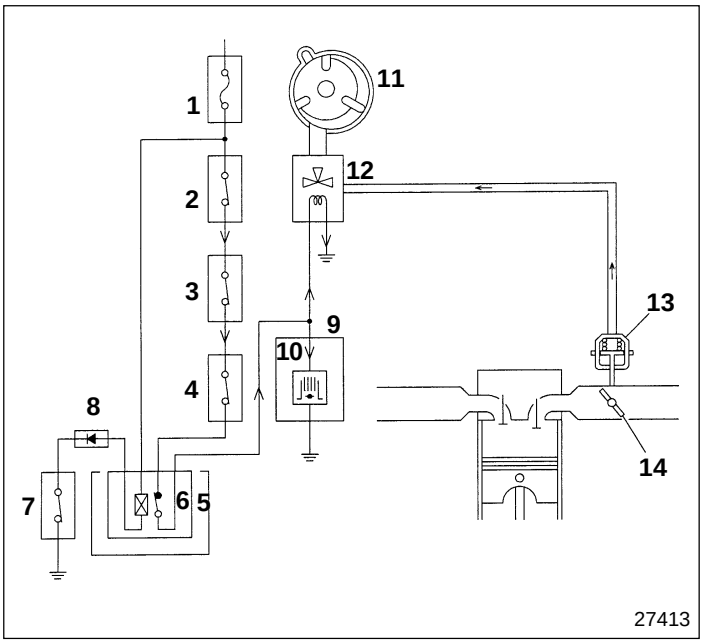
7 Transmission neutral switch
8 Diode
9 Meter cluster
10 Exhaust brake indicator lamp
11 Vacuum pump
12 3-way magnetic valve
13 Exhaust brake unit
14 Butterfly valve

- Excitation of the coil of 3-way magnetic valve **12** closes the atmospheric valve and opens the vacuum valve. This makes the vacuum pump **11** act on exhaust brake unit **13** which closes butterfly valve **14**, activating the exhaust brake.
- If the exhaust brake is activated while the vehicle is stationary, the coolant temperature can rise excessively, overheating the engine. To avoid this, when the transmission is in neutral, transmission neutral switch **7** turns ON, cutting the exhaust brake system.

● When exhaust brake system is activated

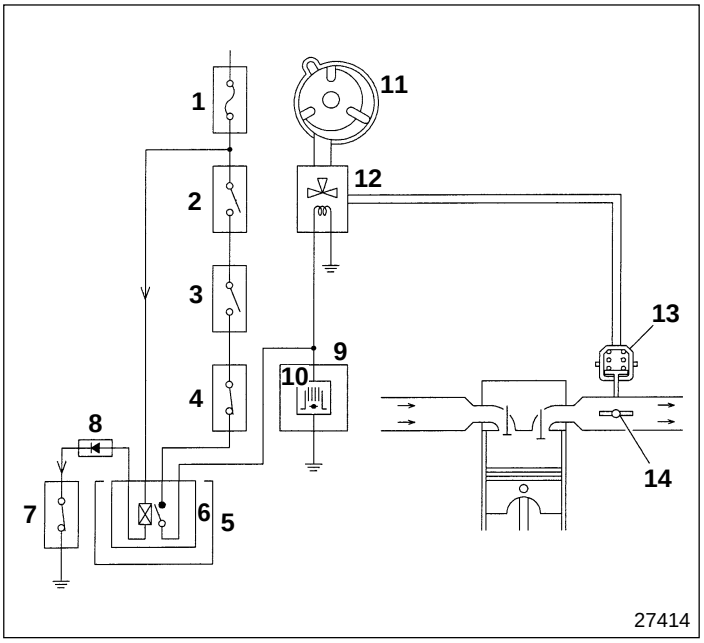


When exhaust brake switch **4** is turned on, the current flows as illustrated to activate the exhaust brake.

Fuse **1**→Clutch switch **2**→Accelerator switch **3**→Exhaust brake switch **4**→Exhaust brake cut relay **6**⟶→3-way magnetic valve **12**→Ground

⟶→Exhaust brake indicator lamp **10** (ON)→Ground

● When the exhaust brake system is released



When the accelerator pedal or clutch pedal is depressed while the exhaust brake is working, all switches **3**, **2** turn off, shutting off the current, releasing the exhaust brake.

● When clutch pedal is depressed

Fuse **1**→Clutch switch **2** (OFF)→Since no current flows, the circuit turns off and the exhaust brake is released.

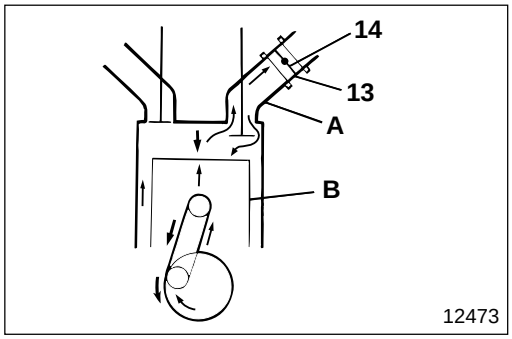
● When accelerator pedal is depressed

Fuse **1**→Clutch switch **2**→Accelerator switch **3** (OFF)→Since there is no grounding, current does not flow, so the exhaust brake is released.

● Releasing exhaust brake system by placing transmission in neutral

Fuse **1**→Exhaust brake cut relay **6** excitation→Transmission neutral switch **7**→Ground
Fuse **1**→Clutch switch **2**→Accelerator switch **3**→Exhaust brake switch **4**→Exhaust brake cut relay **6** (OFF)→Beyond this, current does not flow so the exhaust brake is released.

● Working principle of exhaust brake



When butterfly valve **14** of exhaust brake unit **13**, in exhaust pipe **A**, is closed, the pressure in the exhaust pipe rises. The pressure rises further in the exhaust stroke, generating a force that pushes back piston **B**, the exhaust braking force.

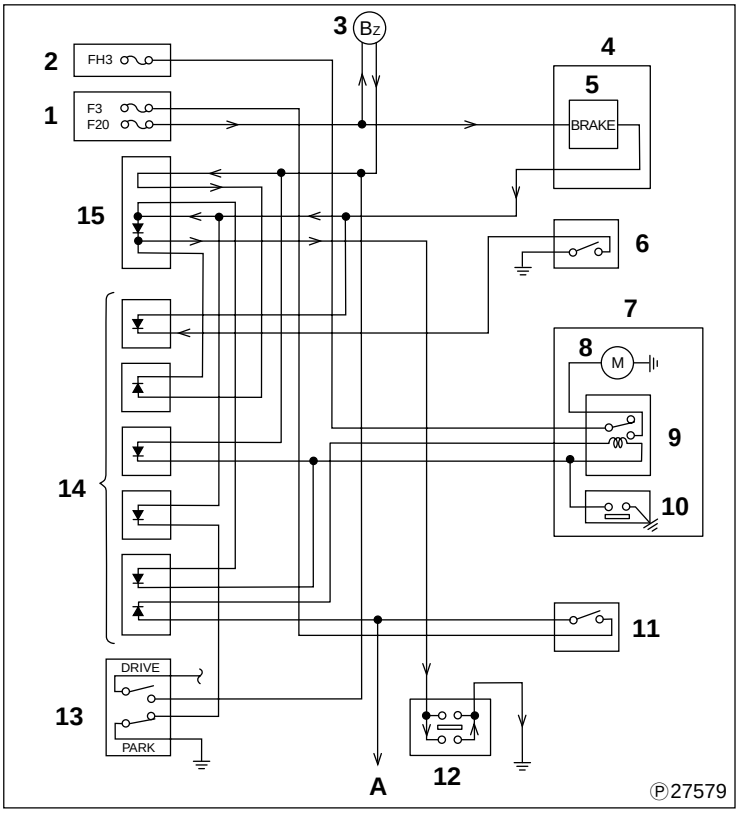
● Power steering fluid level warning circuit



- Since the fluid pressure of the power steering fluid is also used for brake booster (hydraulic booster) **7**, the power steering fluid level warning circuit is connected to warning buzzer **3** and brake warning lamp **5**.
- When the power steering fluid level drops below the **"MIN"** level or rises above the **"MAX"** level of the power steering oil tank, power steering fluid level sensor **12** is turned ON, and the flow of current at such time is as follows.

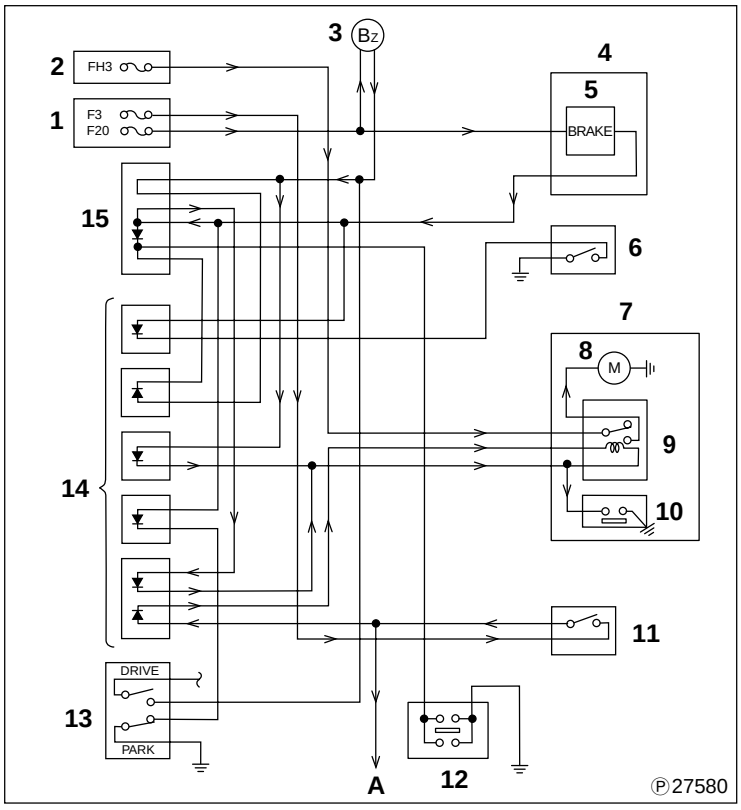
As a result warning buzzer **3** sounds and warning lamp **5** lights to warn the driver.

● **Brake booster (hydraulic booster) fail-safe system**



- If there is a fluid leakage in the power steering system piping and hydraulic pressure is lost, the brake booster (hydraulic booster) fail-safe system will act in the following manner.

  Flow switch **10** is turned ON and the flow of current is as follows.

  Fuse **1** → Warning buzzer **3**

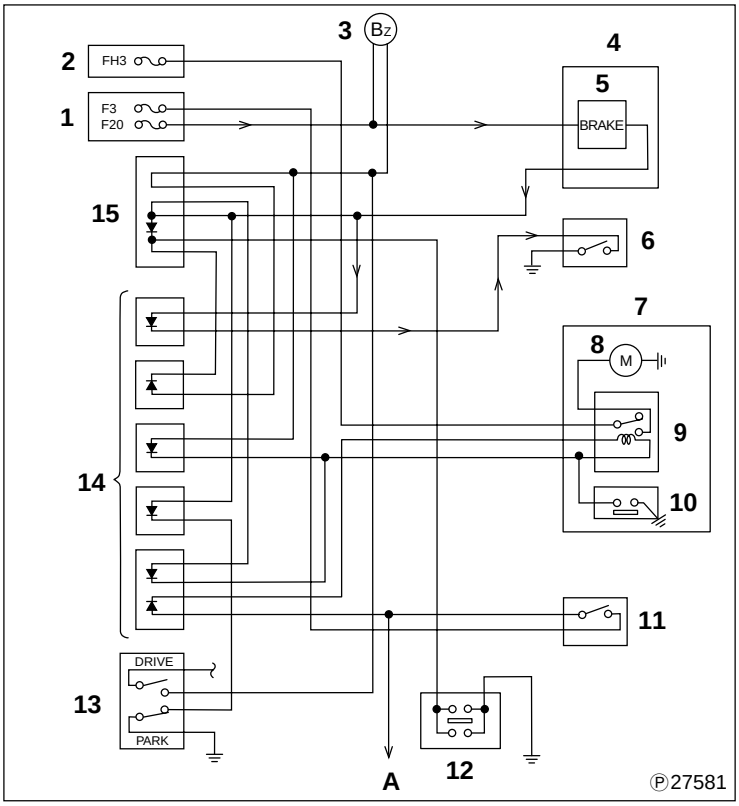
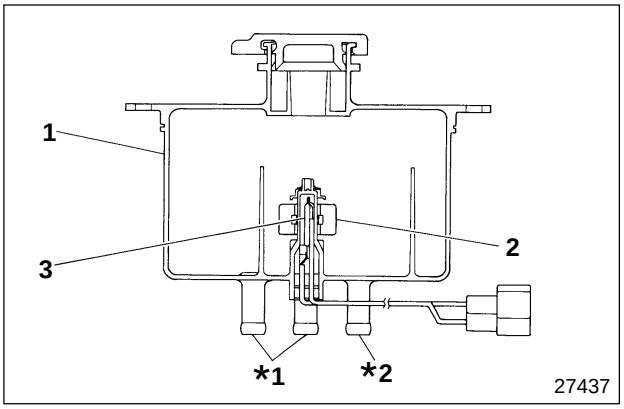
  As a result emergency pump motor **8** starts operating, maintaining the hydraulic pressure during an emergency.

● **Brake fluid warning circuit**



- When the brake fluid in the fluid tank drops below the specified level, brake fluid level switch **6** in the fluid tank turns on, brake warning lamp **5** lights.

● **Brake fluid level switch**



1 Fluid tank
2 Float
3 Brake fluid level switch
***1** : For brakes

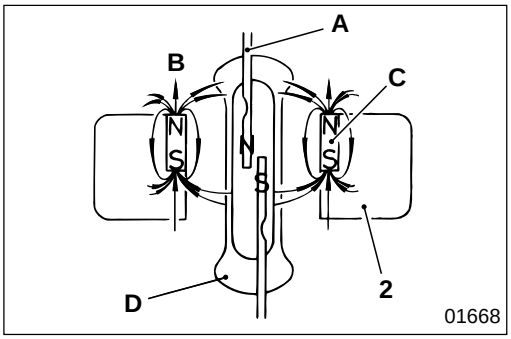
- Brake fluid level switch **3**, installed on fluid tank **1**, monitors the brake fluid level in the fluid tank. If the brake fluid level drops below the specified level, float **2** moves and lights up the warning lamp within the meter cluster to alert the driver.



- If the brake fluid level in fluid tank **1** drops and float **2** drops lower than level **L**, magnetic force **B** that passes through the contact point (ferromagnetic body **A**), increases generating north and south poles at the ends of the contact points. Therefore, the contact points pull each other and overcome the repercussive force of the springs of the contact points, forming an electric circuit.

Special tools

Unit : mm {in.}

Location	Tool name and shape	Part No.	Application
1	Vinyl hose 	MH033102	Air bleeding

WARNING

- **The clutch fluid system and the brake fluid system use the fluid tank in common.**
- **You must use new brake fluid (SAE J17031 or FMVSS No. 116 DOT 3). Do not add different quality fluid or mineral oil (gas oil, engine oil, gear oil, automatic transmission fluid, etc.) to the clutch system, because this will cause the rubber parts of the clutch system and brake system to swell, resulting in faulty clutch operation, as well as ineffective braking and brake dragging.**
- **Do not allow foreign particles or water to become mixed into the brake fluid when refilling, because this will result in ineffective clutch and brake operations.**
- **If you use a mug for adding brake fluid, keep it solely for that purpose.**

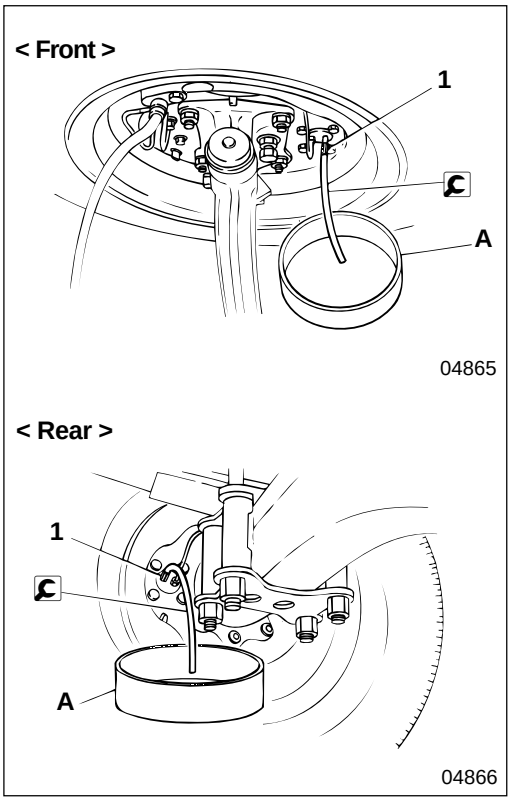
CAUTION

- **Be careful not to splash brake fluid on related parts as this could damage the paintwork.**
- **Be sure to wipe off brake fluid immediately if you splash it on the paintwork.**

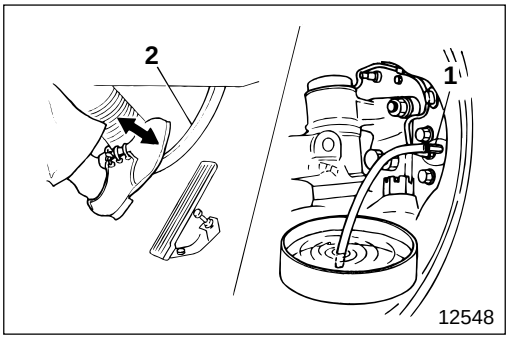
NOTE

Supply and maintain the brake fluid level to the "MAX" level of the fluid tank.

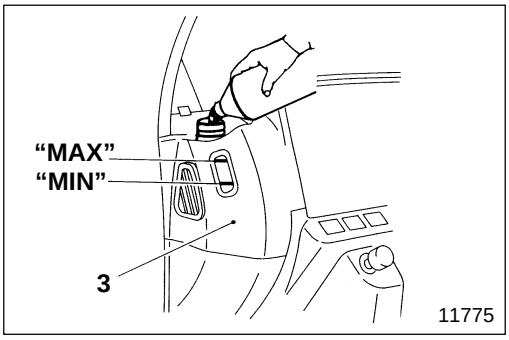
- Start engine and let it idle until brake fluid replacement is completed.



- Attach one end of vinyl hose to air bleeder **1** and place the other end in container **A**.



- Loosen air bleeder **1** and depress brake pedal **2** to drain brake fluid completely.



- Maintain a supply of new brake fluid up to the "**MAX**" level of fluid tank **3**, depress the brake pedal repeatedly until the old brake fluid of the brake system is replaced with new fluid.

- Bleed air from the brake system.

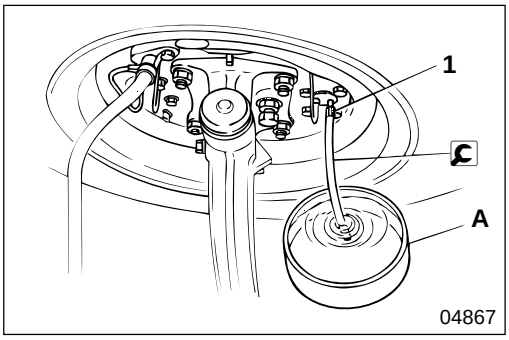
NOTE

- **Supply and maintain brake fluid to the "MAX" level of the fluid tank.**
- **Make sure you maintain brake fluid at the "MAX" level of the fluid tank since the brake fluid level drops during air bleeding.**



- Start engine and let it idle until brake fluid replacement is completed.
- Attach one end of 🔧 vinyl hose to air bleeder **1** of the wheel brake. Place free end in container **A** filled with brake fluid.

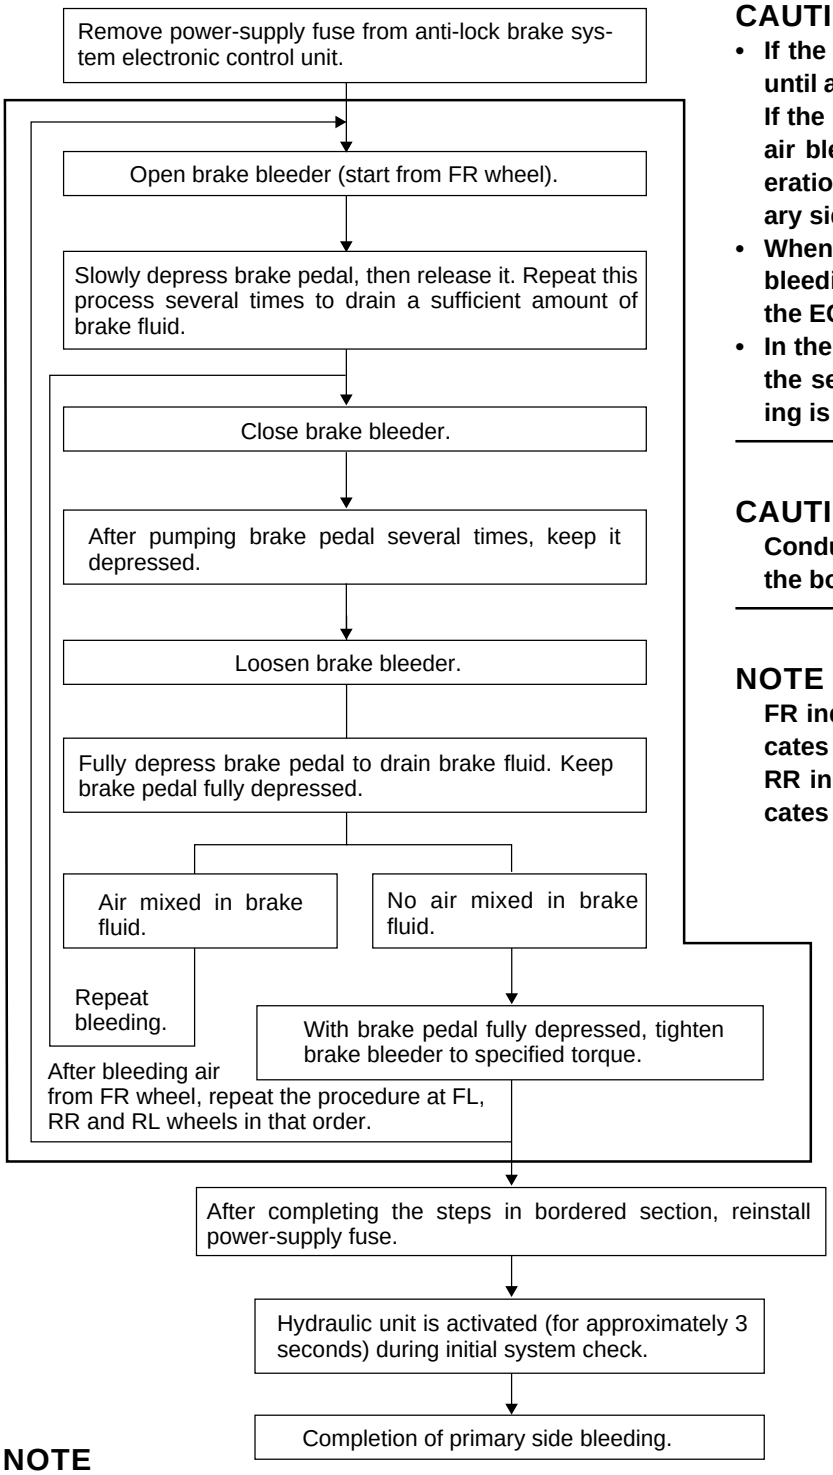
ON-VEHICLE INSPECTION AND ADJUSTMENT

(1) Air bleeding during regular maintenance, and hydraulic unit replacement

When air bleeding is conducted during regular maintenance or when the hydraulic unit is replaced, brake fluid flows into the secondary side (operating circuit) of the hydraulic unit. Therefore, bleed the primary side (normal circuit) by following the procedures below. In the event air enters the secondary side, bleed air by following the procedures described in (2).



CAUTION

- **If the battery is disconnected, do not reconnect until air bleeding of the primary side is complete. If the battery is reconnected before primary side air bleeding is complete, the system check operation is activated and air can enter the secondary side.**
- **When the battery must be connected prior to air bleeding, remove the power-supply fuse from the ECU.**
- **In the event air enters the secondary side, bleed the secondary side after primary side air bleeding is complete.**

CAUTION

Conduct the air bleeding operation described in the bordered section at every wheel.

NOTE

FR indicates front-axle right wheel, and FL indicates front-axle left wheel.
RR indicates rear-axle right wheel, and RL indicates rear-axle left wheel.

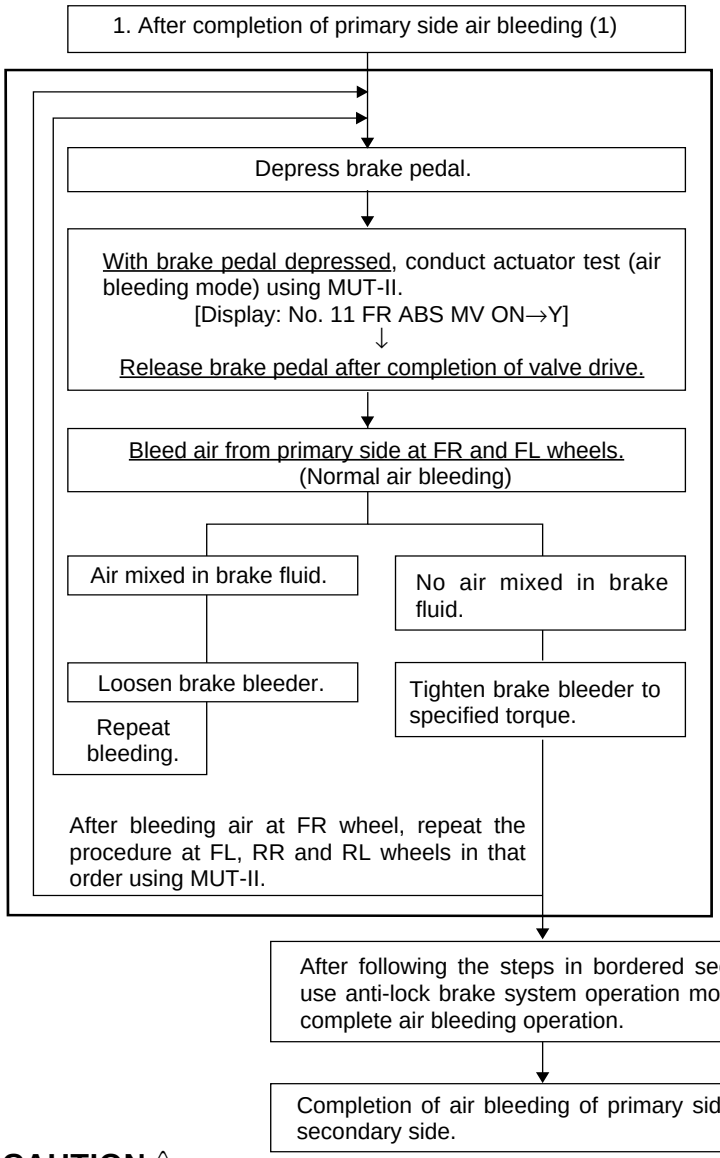
NOTE

- **The primary side (normal circuit) is a hydraulic circuit formed when the system is in non-operation.**
- **The secondary side (operating circuit) is a hydraulic circuit which connects with the primary side only when the system is in operation (when the system is in non-operation, the secondary side is disconnected from the primary side).**

(2) Air bleeding of secondary side

If the system starts operating before air bleeding of the primary side is complete, air can enter the secondary side. In the event the system accidentally starts before the completion of primary side air bleeding, follow the procedures below to bleed air. If air enters the secondary side, air flows into the primary side when the system starts, and this can extend the brake pedal stroke.
During air bleeding, use the MUT-II to conduct an actuator test (anti-lock brake system operation mode) at all wheels.

Use the MUT-II when bleeding air from the secondary side.



CAUTION⚠

Conduct air bleeding operation described in the bordered section at every wheel by using the anti-lock brake system operation mode.

CAUTION⚠

Bleed air from wheels other than FR according to the directions below.

(Refer to NOTE below)

For FL wheel
[Display: No. 12 FL ABS MV ON→Y]
↓
Bleed air from primary side at FR and FL wheels.

For RR wheel
[Display: No. 13 RR ABS MV ON→Y]
↓
Bleed air from primary side at RR and RL wheels.

For RL wheel
[Display: No. 14 RL ABS MV ON→Y]
↓
Bleed air from primary side at RR and RL wheels.

CAUTION⚠

- **Avoid continuous execution of the actuator test (anti-lock brake system drive) using the MUT-II; otherwise, excessive heating of the anti-lock brake system motor, valve and other parts can cause hydraulic unit damage.**
- **Do not conduct the actuator test with the MUT-II while bleeding air from the primary side; otherwise, air can enter the secondary side from the primary side.**
- **When mixing of air was found after air bleeding is conducted to correct an excessive brake pedal stroke, bleed air from the secondary side, too.**

NOTE

- **For the MUT-II operation for the actuator test during air bleeding, refer to section 4.**
- **If a drive operation is conducted for the FR and RL wheels at one time using the MUT-II, subsequent air bleeding of the primary side conducted at each wheel will not remove air from the secondary side.**

[Inspection]

NOTE

Be sure to inspect at two points for each wheel per side.

- Remove check hole plug **1** from the backing plate.
- Inspect through check hole **A** whether brake lining **2** is worn to the point of side shoulder **B** of the brake lining (the limit).
- If the measured value is lower than the limit, replace brake lining **2** on the same axle as a unit.
- After inspection, be sure to reinstall check hole plug **1**.

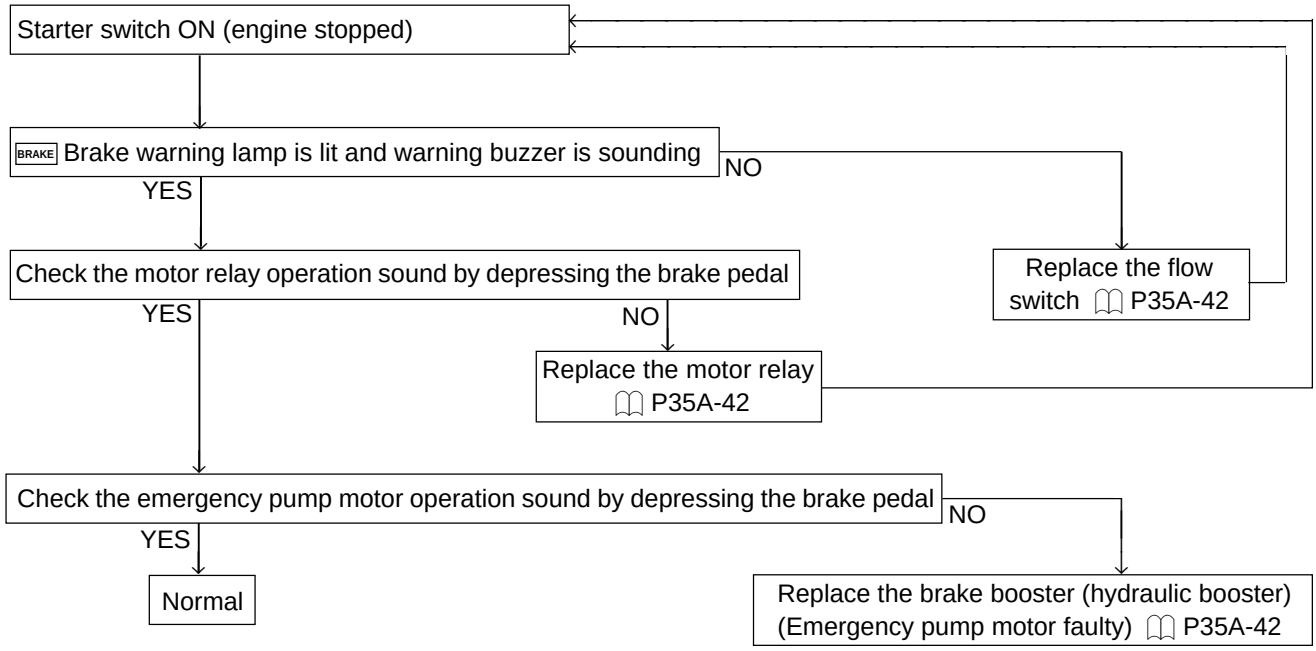
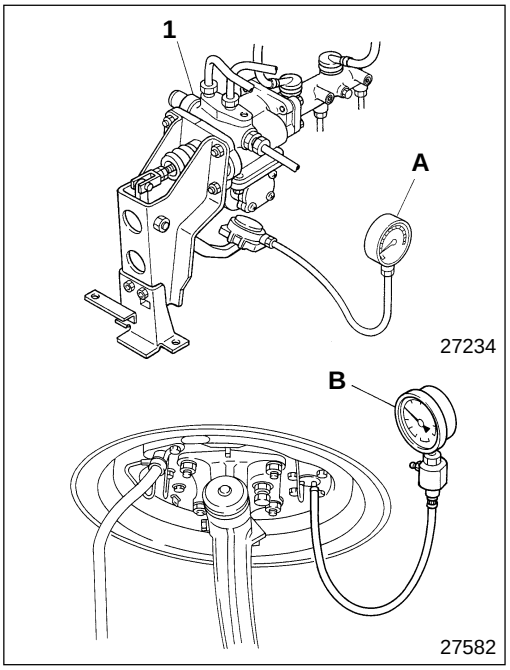
Inspection of Brake Booster (Hydraulic Booster)

(1) Inspection of electric equipment

Perform inspection in accordance with the flow-chart below. Make sure the power steering fluid level sensor is working properly and power steering oil tank fluid level is normal. Make sure the parking brake is working properly and the wheels are choked during inspection.





(2) Performance inspection

- Mount foot pressure meter **A** on the brake pedal, remove the front wheel brake air bleeder and after installing oil pressure gauge **B**, bleed the air from the pressure gauge.
- Carry out a performance evaluation test on the power steering system and make sure hydraulic pressure in the power steering fluid system is at a normal level. Gr 37
- If the above proves normal, check to make sure the hydraulic pressure of the front wheel brakes in response to foot pressure on the brake pedal is in conformity with the performance characteristics chart.
  If faulty, replace brake booster (hydraulic booster) **1**.

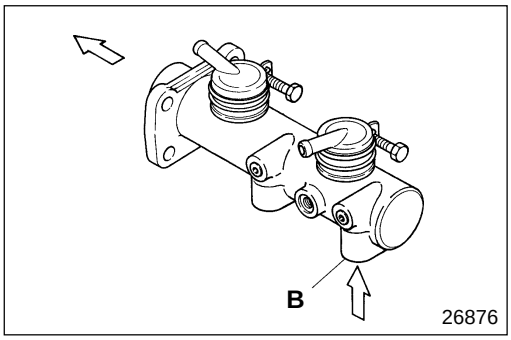
[Removal]

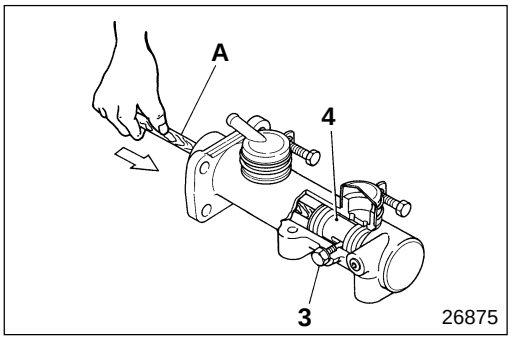
- Using rod **A**, push in secondary piston assembly **4**, then loosen set bolt **3**.



- Feed compressed air via discharge port **B** that leads to the rear wheel brake to extract secondary piston assembly **4**.

WARNING⚠

You must apply compressed air gradually when you remove secondary piston assembly 4. If you applied compressed air strongly at one time, the secondary piston assembly would be violently ejected.



[Installation]

Using rod **A**, push in secondary piston assembly **4**, then tighten set bolt **3** at specified torque.

● Adjustment after assembly

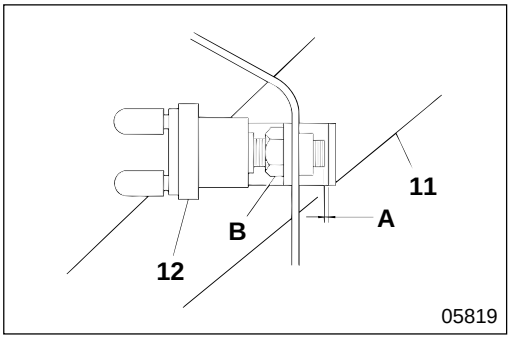
- Adjustment of brake pedal installation height
  By turning operating rod **C** of brake booster (hydraulic booster) **4**, adjust height **B** from the center of pedal pad **10** to the underside of instrument panel **A** to the standard value, then secure in place using nut **D**.

WARNING⚠

Make sure, when brake pedal 11 is depressed fully, that operating rod C of brake booster (hydraulic booster) 4 functions as the stopper and the pedal does not come to a stop by hitting against the floor panel, since this will reduce brake effectiveness.

- Inspection of brake pedal full stroke
  Make sure that full stroke **E** when brake pedal **11** is depressed fully conforms to the standard value.
  If there is any fault, adjust the installation height of the brake pedal.

- Inspection of play towards brake pedal 🕮 P35A-34



12 Adjustment of stop lamp switch

Turn stop lamp switch **12** to adjust clearance **A** between the top of the thread area of the stop lamp switch and the stopper of brake pedal **11** to the standard value, and fasten with lock nut **B**.

WARNING⚠

Make sure, when brake pedal 11 is released, that stop lamp switch 12 does not stop the pedal, since this will cause the brake to drag.

◆ Service procedure

● **Initial adjustment of brake shoe clearance after installation**

- Jack up the front wheels, and make sure that there is no play in the hub bearings.
- Insert screwdriver **B** into adjusting hole **A** and turn adjuster **C** in the direction of the arrow marked on backing plate **21** until the wheel drags slightly when turned by hand.

NOTE

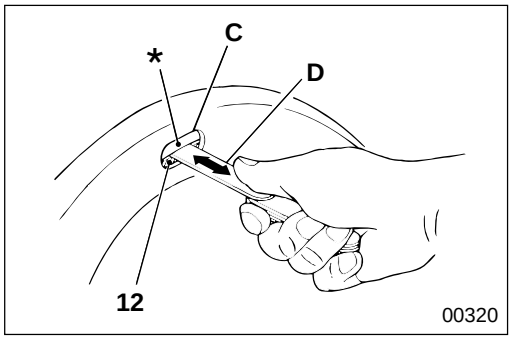
- **Be sure to adjust the clearance at two points for each wheel per side.**
- **The arrow mark on backing plate 21 is near adjusting hole A.**

- After depressing the brake pedal several times, release it and make sure that the wheel drags lightly when turned by hand. If the wheel turns without stress, repeat the above steps. Slacken off adjuster **B**, in the reverse direction to the arrow mark, by eight or nine notches.

NOTE

Be sure to adjust the clearance at two points for each wheel per side.

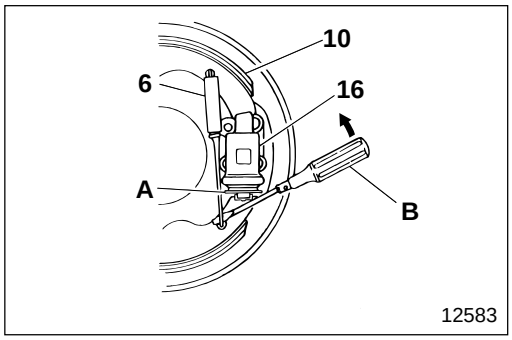
- Make sure that the wheel does not drag when turned by hand. If the wheel drags, repeat the above steps.



- Insert feeler gauge **D** between brake drum ***** and brake lining **12** through check hole **C**, and make sure that a little resistance is felt when the feeler gauge is pulled out or pushed in.

NOTE

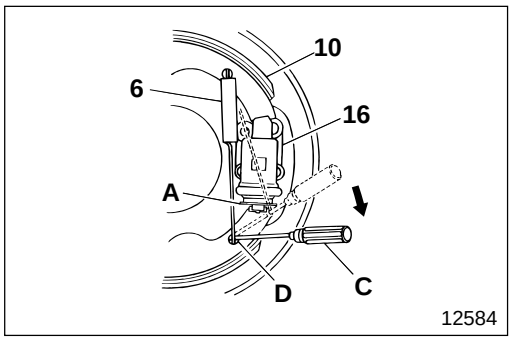
Be sure to adjust the clearance at two points for each wheel per side.



6 Return Spring

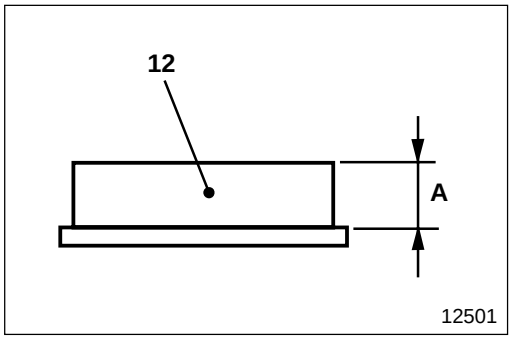
[Removal]

To remove return spring **6**, place screwdriver **B** on the hook of the return spring, then pry and remove the return spring making use of wheel cylinder assembly **16** adjuster **A** as a fulcrum.



[Installation]

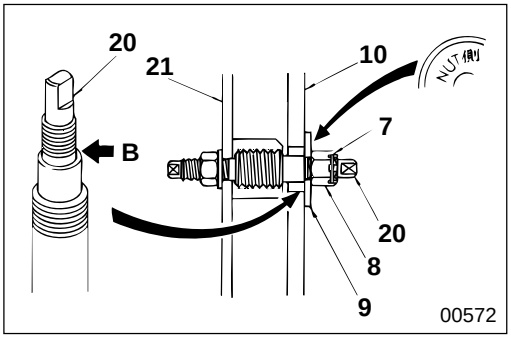
- Install the shorter hook end of return spring **6** in brake shoe assembly **10** at the side opposite to adjuster **A** of wheel cylinder assembly **16**.
- Insert a small Phillips screwdriver **C** into the hook of return spring **6**, insert the tip of the screwdriver into return spring installation hole **D** of the brake shoe assembly to pry on the return spring.



10 Brake shoe assembly

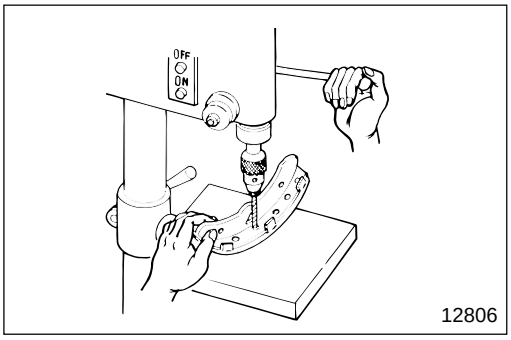
[Inspection]

If thickness **A** of brake lining **12** is lower than the limit replace the brake lining on the same axle as a unit.



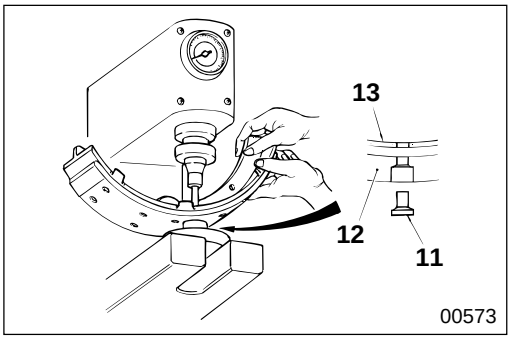
[Installation]

- Install brake shoe assembly **10**.
- Insert washer **9** with the side stamped “NUT 側” facing outside, screw down holder pin nut **8** until washer hits stepped area **B** of holder pin **20** gently, then slacken off the nut within the 0 to 60° limit until the nut is aligned with the first split pin hole.
- Insert split pin **7**, and bend it securely.



12 **Brake lining**

[Removal]



[Installation]

- Clean the mounting surfaces of brake lining **12** and brake shoe **13** with cleaning fluid and dry them.
- Insert rivets **11** from brake lining **12** side, and caulk the rivets at the specified load so that there is no clearance between brake shoe **13** and the brake lining.

  Caulking load for rivets : 17 to 19 kN {3750 to 4190 lbf, 1700 to 1900 kgf}

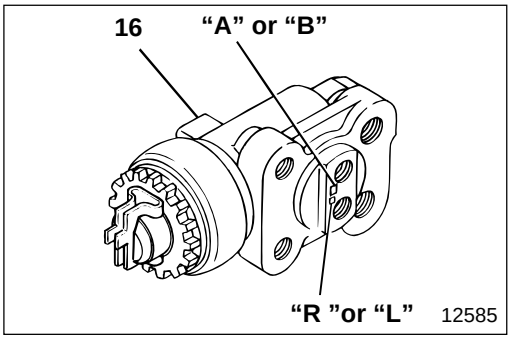
- Make sure that you inspect contact with the inner surface of brake drum ***** after you replace brake linings **12**. If contact is incorrect, correct with the brake assembled.

WARNING⚠

Do not leave lubricant on the surface of brake lining 12 because this reduces braking performance.

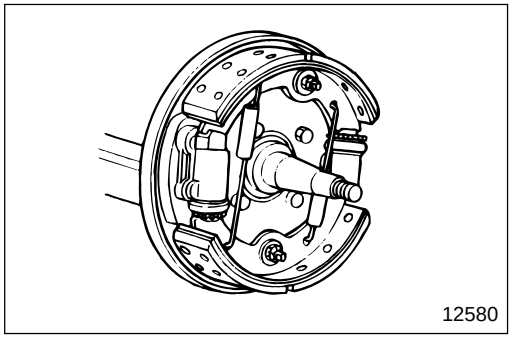
CAUTION⚠

Make sure that the type of brake linings 12 you fit are suitable for the intended use of the vehicle. Make sure that you fit identical size and color coated linings on the left and right sides of one shaft.



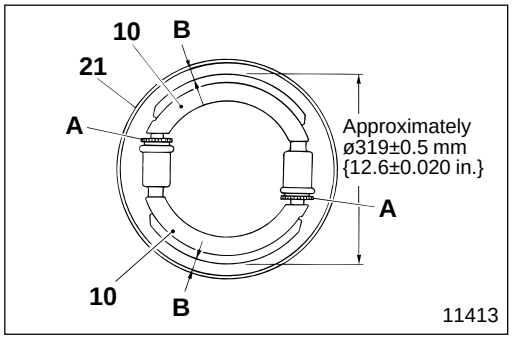
16 **Installation of wheel cylinder assembly**

Identification mark	Installation position
RA	Front of front axle right wheel
RB	Rear of front axle right wheel
LA	Front of front axle left wheel
LB	Rear of front axle left wheel

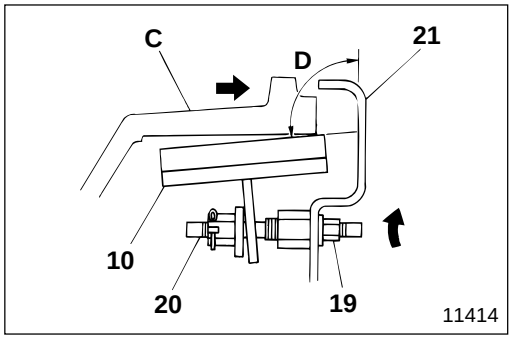


20 **Adjustment of holder pin**

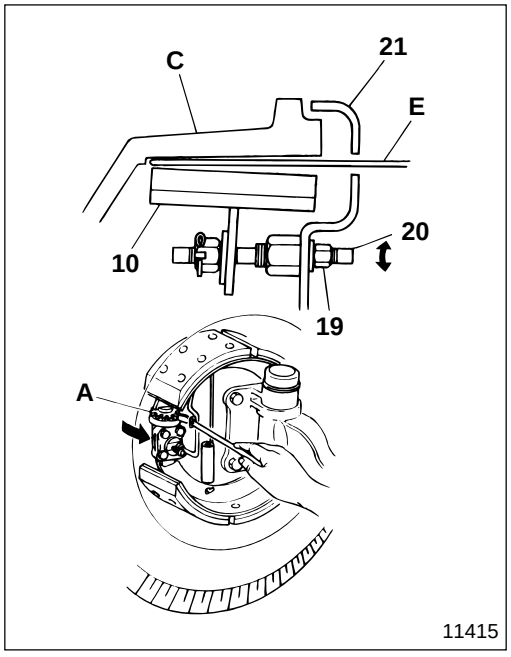
- Install the front wheel brake assembly on the front axle. Gr 26



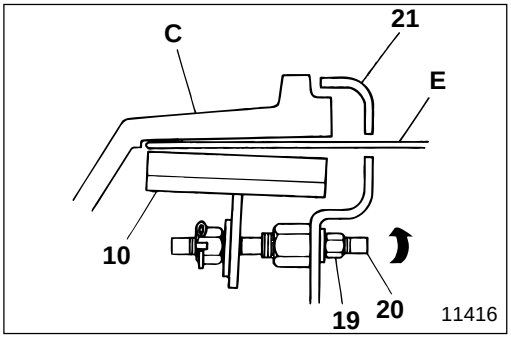
- Turn adjuster **A** to adjust the outer diameter to approximately ø319±0.5 mm {12.6±0.020 in.}.
- Then, move brake shoe assembly **10** to adjust clearance **B** evenly.



- Install hub and drum assembly **C** on the front wheel brake assembly. Gr 26
  At this time, the hub and drum assembly cannot be inserted in the specified position if squareness **D** is 90° or more, so loosen nut **19** and turn holder pin **20** to adjust the squareness to as close to 90° as possible.
- Bleed the brake system. P35A-30



★• Turn adjuster **A** to widen brake shoe assembly **10** until 0.2 mm {0.0079 in.} feeler gauge **E** cannot be pulled out easily.
★• Loosen nut **19** and turn holder pin **20** to the right or left so that feeler gauge **E** can be pushed in or pulled out easily.
- Repeat the above steps (marked ★) until feeler gauge **E** cannot be pushed in or pulled out easily.
- Depress the brake pedal a few times lightly to equalize clearance **B** (adjusted in the previous section).
- Repeat the above steps (marked ★) until feeler gauge **E** cannot be pushed in or pulled out easily.



- If feeler gauge **E** cannot be pushed in or pulled out easily it is because it is making contact over the full width of brake shoe assembly **10**.
- Turn holder pin **20** so that when you pull out feeler gauge **E**, in the above condition, and reinsert the feeler gauge, pushing in or pulling out the feeler gauge at the rear is difficult.
- After adjustment, tighten nut **19** at specified torque.

* Correction of brake drum

If the cylindrical accuracy of brake drum * is higher than the limit, or there are seams, correct by machining to the correction limit. Machining of the brake drum should be done with the wheel hub attached as an integral part.

● **Adjustment after assembly**

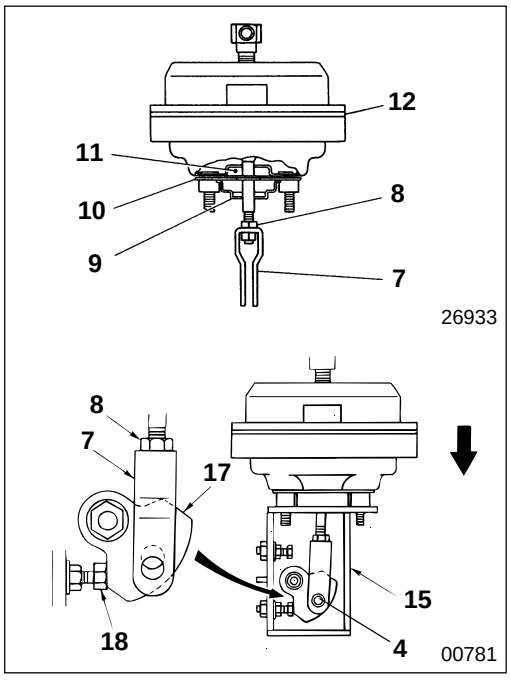
Adjustment of valve when fully-closed

- While applying negative pressure **B** of 87 to 93 kPa {25.6 to 27.5 in.Hg, 650 to 700 mmHg} to vacuum chamber assembly **12**, adjust by turning adjusting bolt **18** so that clearance **D** and **E** between the butterfly valve and body **C** conforms to the standard value.
- After adjustment, tighten lock nut **19** at specified torque.
- Average value of clearance **D, E** = (**D + E**)/2.
- Fully-opened adjustment of butterfly valve **A** is done while valve and bracket assembly **15** is installed.



12 **Vacuum chamber assembly**

[Installation]

- Adjust valve and bracket assembly **15**. 🕮 P35A-65
- Adjust the hole of clevis **7** to position as illustrated.
- Fix clevis **7** using lock nut **8**.

STRUCTURE AND OPERATION
Anti-lock Brake System (ABS)

The anti-lock brake system (ABS) prevents tire slippage due to wheel lockup caused by sudden braking and braking on slippery road surfaces. The anti-lock brake system provides a driver with vehicle controllability and directional stability in braking.

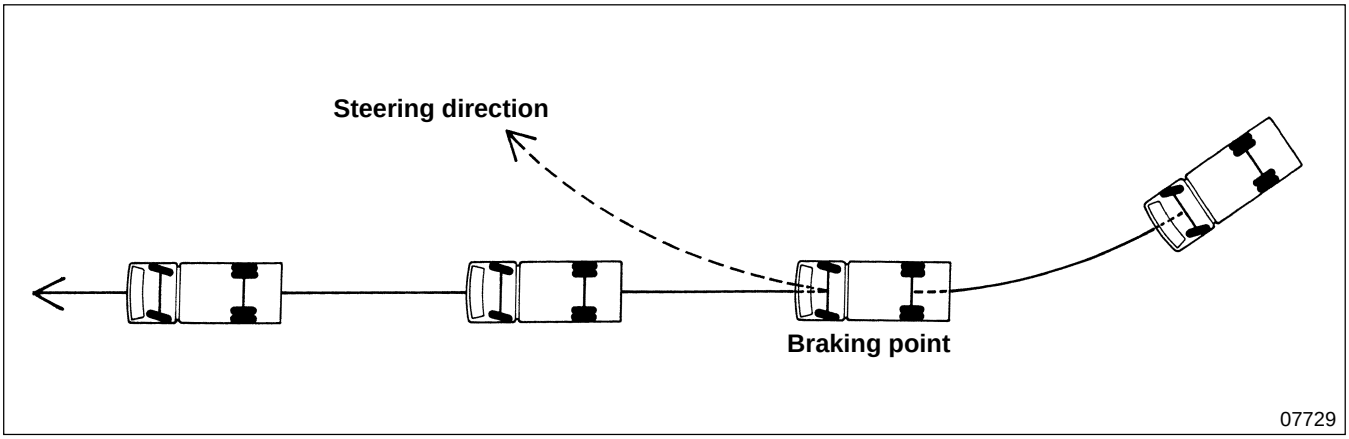
● Wheel lockup

Rotating tires of a moving vehicle have a tendency to continue traveling in the direction of tire rotation. Because of this characteristic, a driver can control the vehicle's traveling direction by moving the front wheels to a desired direction using the steering wheel.

In a vehicle not equipped with an anti-lock brake system, when a driver depresses the brake pedal with full force, the wheels can lock up under certain conditions. Tires in a wheel lockup condition lose the tendency to maintain directional characteristic, and the vehicle starts sliding in a direction of an externally applied force regardless of the tire direction. In other words, when wheel lockup occurs, the vehicle loses its directional stability, disallowing the driver to control the vehicle's movement.

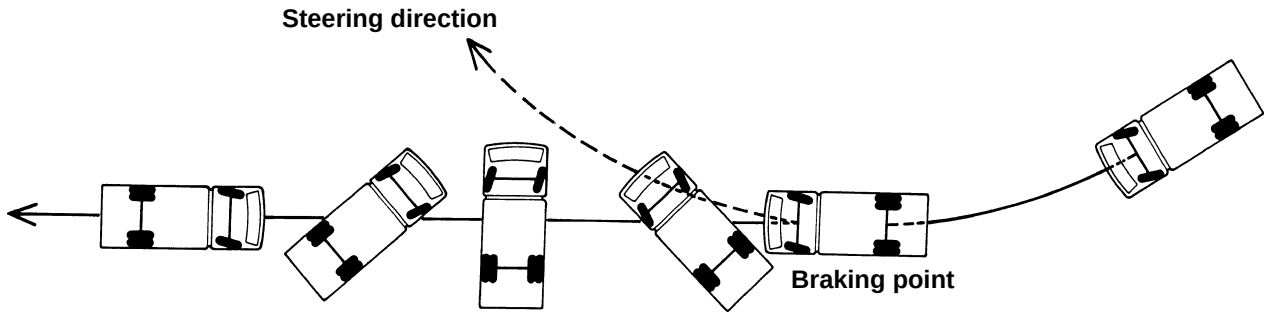
The following shows how a vehicle without anti-lock brake system loses its directional stability when different tires lock up on slippery road surfaces.

● Front wheel lockup (both front tires)



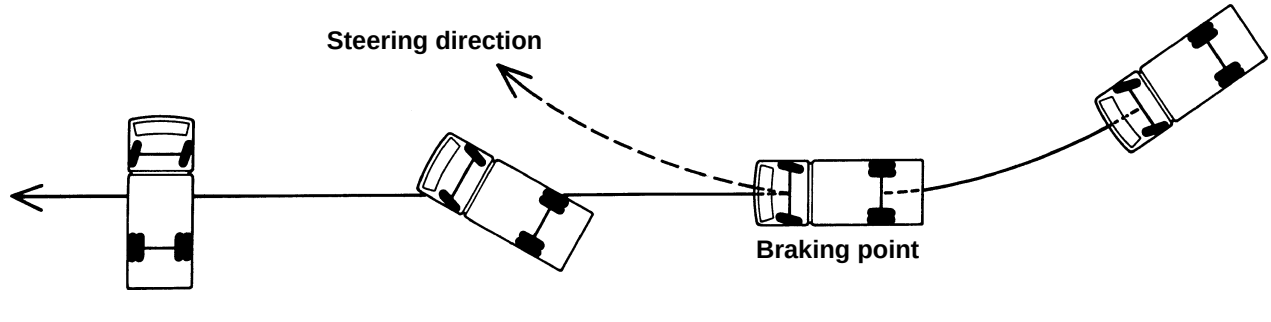
The front tires lose directional stability, but the rear tires try to travel in the direction of rotation since they are not locked up. Because of the front wheel lockup, a steering wheel operation does not change the vehicle's moving direction.

● **Rear wheel lockup (both rear tires)**



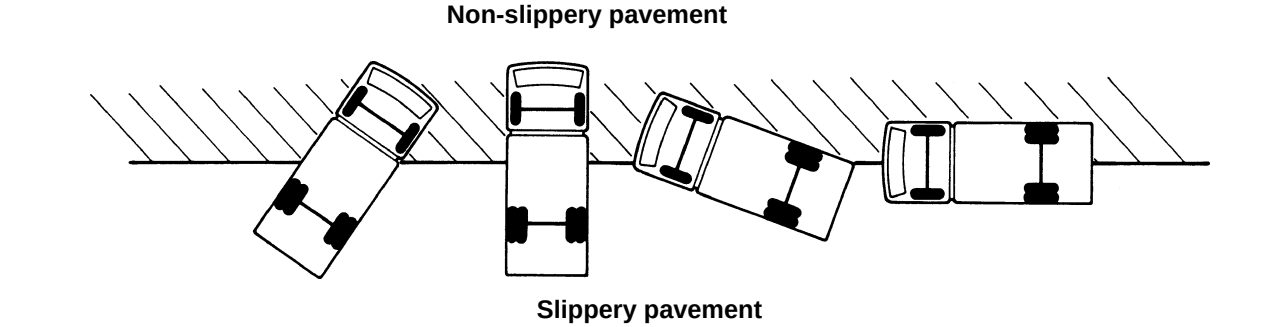
When the steering wheel is operated with the rear wheels in a lockup condition, the front tires try to change the vehicle's traveling direction, but the rear tires slide sideways, causing the vehicle to spin. If wheel lockup occurs in a vehicle traveling in a straight direction, the force of inertia continues to push the vehicle straight ahead from the back of the vehicle due to the lack of stopping force in the rear tires, and the vehicle can spin.

● **All wheel lock up (front and rear tires)**



When wheel lockup occurs in both front and rear tires, all four tires lose directional stability. Therefore, the vehicle slips in the direction of inertia regardless of the steering direction.

● **Wheel lockup on surfaces with split μ factors (road surface with different friction coefficients for right and left tires)**



The tires on a surface with a lower friction coefficient lock up first. The tires in a lockup condition start sliding, thus failing to provide effective stopping force. Due to this imbalance in the stopping power between the right and left tires, one side of the vehicle slows down while the other side continues traveling, thus resulting in the loss of directional stability. When this happens during sudden braking, the vehicle spins.

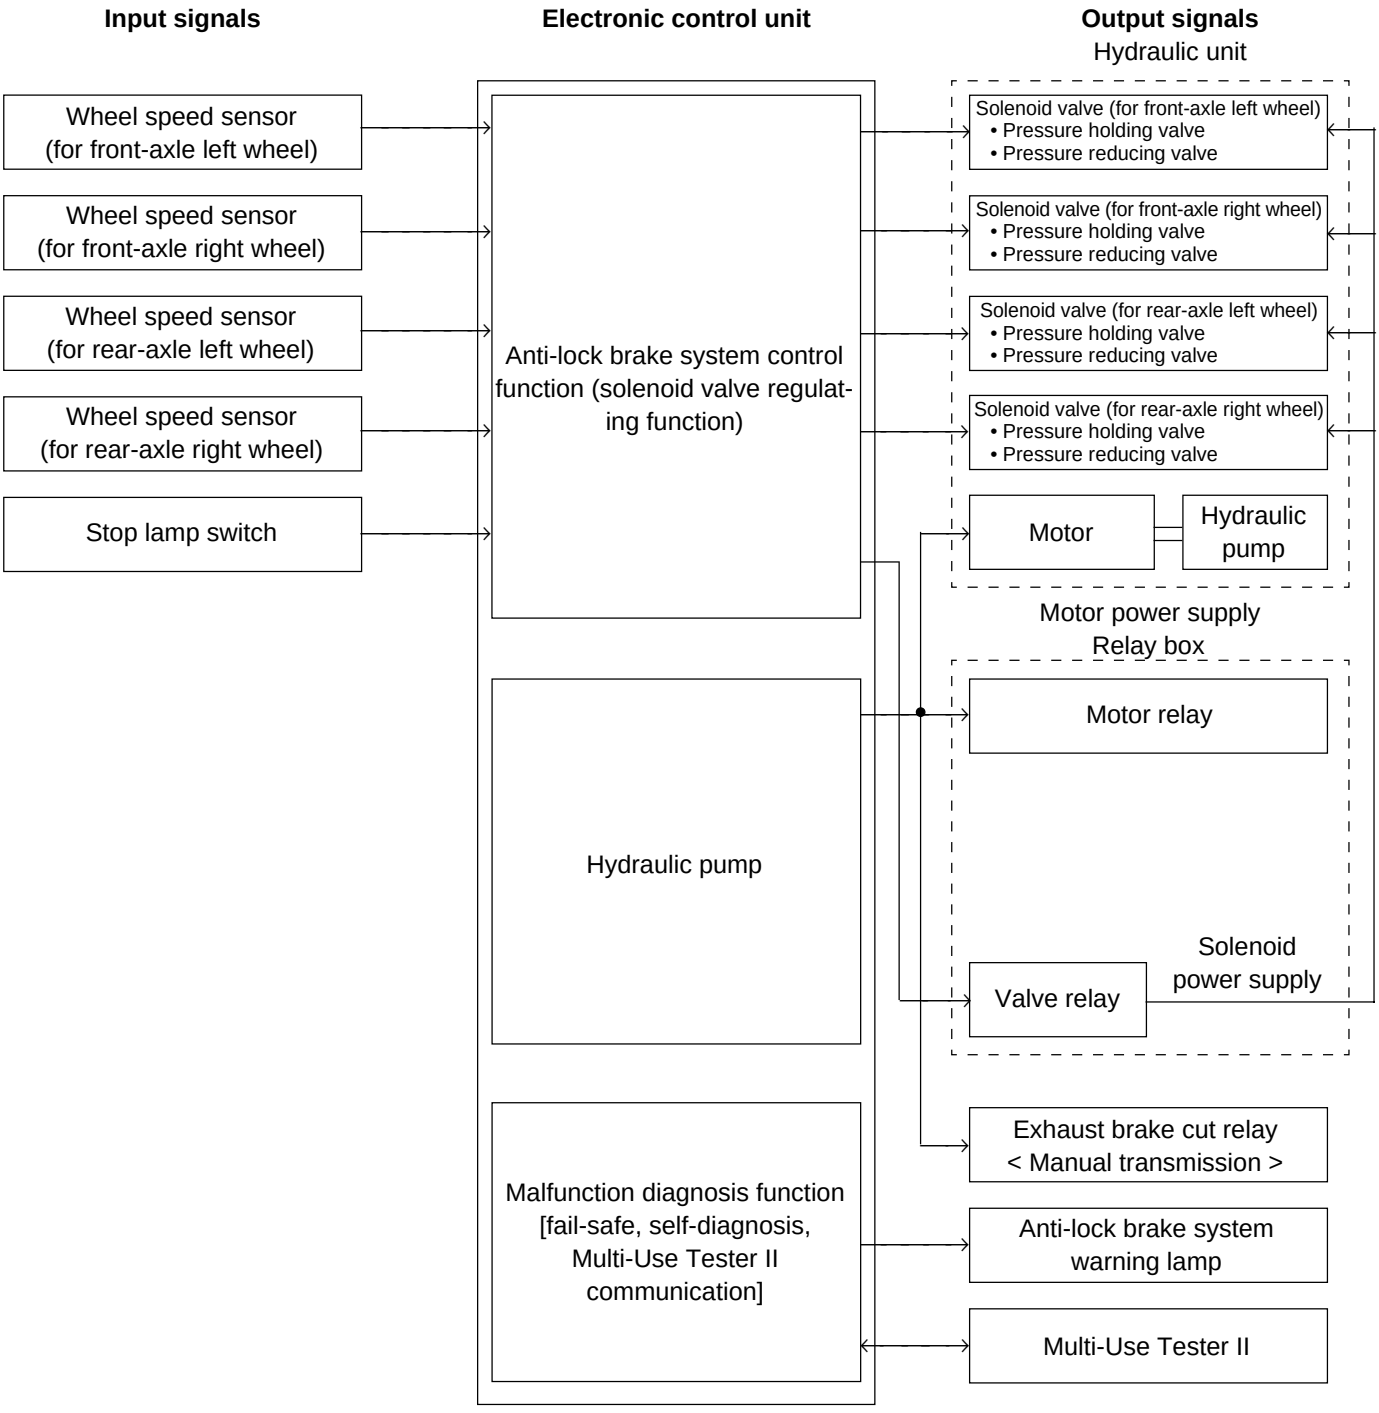
The anti-lock brake system uses wheel speed sensors **8** and electronic control unit **5** to monitor the rotating speed of each wheel. When the wheel speed exceeds the preset deceleration speed or slip rate, the electronic control unit detects it as a tendency leading to wheel lockup, and sends control signals to hydraulic unit **6** and relay box **7**. The signals activate the solenoid valves to reduce the brake fluid pressure in the wheel brakes and ease the braking force to prevent wheel lockup. Then, when the wheel speed increases, wheel speed sensors **8** send signals to the solenoid valves in hydraulic unit **6** by way of electronic control unit **5** to increase the brake fluid pressure in the wheel brakes to augment the braking force. This control cycle is repeated to prevent wheel lockup on slippery pavements and ensure the vehicle's directional stability during braking. The 4-sensor 4-channel anti-lock brake system uses four wheel speed sensors **8**, which are located at the front and rear wheels, to control each of the four wheels.

● **Anti-lock brake system function**

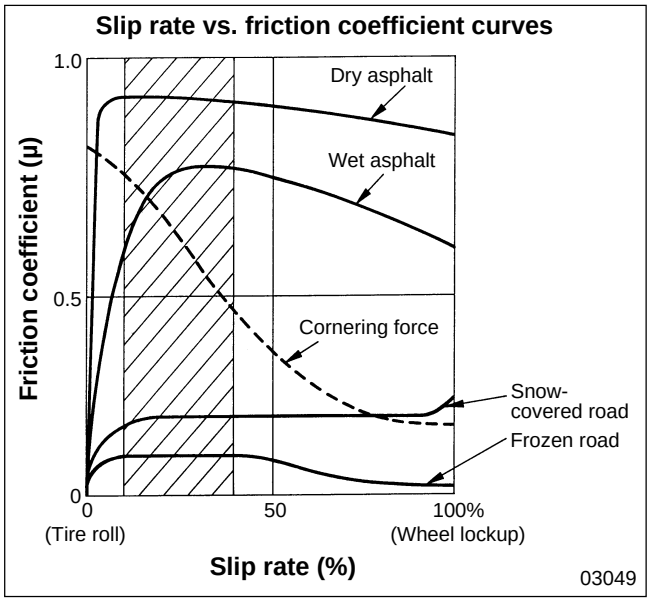


● **Anti-lock brake system control function**

To provide optimum stopping power, the anti-lock brake system controls the braking force based on the slip rate determined by the relationship between the wheel speed and the vehicle speed. When the brake is applied, the resulting force slows down the wheel rotation, thus reducing the vehicle speed. However, inertia acts on the vehicle and tries to maintain the vehicle's forward movement despite the stopping force applied by the tires. When there is a difference between the wheel speed and vehicle speed, slipping occurs. The degree of slippage is expressed by a slip rate.

$$\text{Slip rate (\%)} = \frac{\text{Vehicle speed} - \text{Wheel speed}}{\text{Vehicle speed}} \times 100$$

When the slip rate is 0%, there is no slippage between the tires and pavement. The slip rate of 100% refers to a wheel lockup condition.



The graph shows the time-based changes in the friction coefficient of a rolling tire during the process of wheel lockup. When the brake is applied gradually while the tires are rotating on pavement, the tires begin to slip while in rotation.

When the brake is applied harder, the tires stop rotating and start to slide on the pavement. This condition is called wheel lockup.

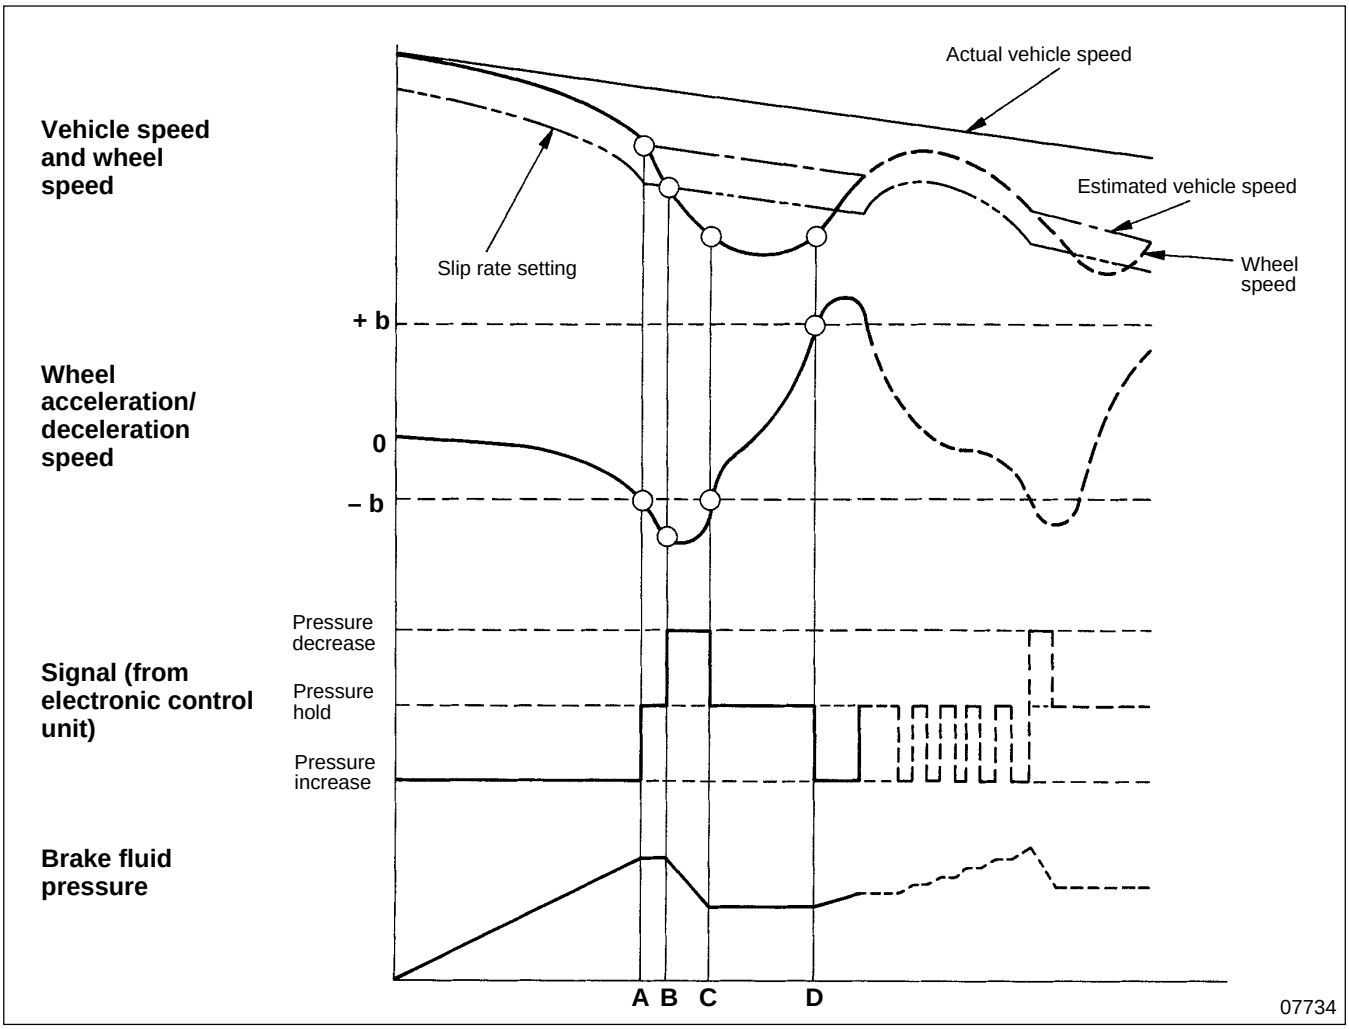
The friction coefficient is highest when the slip rate is within the shaded area on the graph.

In other words, tires provide maximum friction when the braking force is appropriately controlled to maintain the slip rate in the range indicated by the shaded area on the graph, rather than when the brake is applied at full force.

In a vehicle equipped with anti-lock brake system, the electronic control unit and hydraulic unit adjust the braking force and maintain it within the shaded area on the graph where the friction coefficient is high, thus preventing tire slippage and ensuring braking stability.

Anti-lock Brake System Operation

● **Anti-lock brake system control characteristic curve**



The above anti-lock brake system control characteristic graph shows the time-based changes in vehicle speed, wheel acceleration/deceleration speed and brake fluid pressure level during braking.

- When the wheel deceleration speed exceeds the speed setting **– b** at point **A**, the electronic control unit sends a signal to maintain the brake fluid pressure at the same level.
  At the same time, the electronic control unit estimates the vehicle speed according to a programmed calculation method.
- When the vehicle speed decreases further and the slip rate exceeds the setting at point **B**, the electronic control unit detects it as a tendency leading to wheel lockup, and sends a signal to reduce the brake fluid pressure.
- When the wheel speed increases because of the reduced brake fluid pressure and the wheel speed exceeds the setting **– b** at point **C**, the electronic control unit sends a signal to maintain the brake fluid pressure at the same level.
- When the wheel speed increases further and the wheel speed exceeds the setting **+ b** at point **D**, the electronic control unit determines that there is no risk of wheel lockup and sends a signal to increase the brake fluid pressure.

By repeating the above control cycle, the anti-lock brake system prevents wheel lockup and provides maximum friction between the tires and pavement to ensure high stability during braking.

● **Anti-lock brake system and exhaust brake system**

On slippery road surfaces, activation of the exhaust brake system can result in wheel lockup. If the exhaust brake activates during an anti-lock brake system braking operation, proper braking function cannot be provided by the anti-lock brake system.
To prevent this, the exhaust brake system is deactivated during anti-lock brake system operation even when the exhaust brake switch is turned ON.
When the anti-lock brake system stops providing its function, the exhaust brake system becomes operable if the exhaust brake switch is ON.

The solenoid valves and the motor are activated as shown in the following table by the control signal from the electronic control unit.

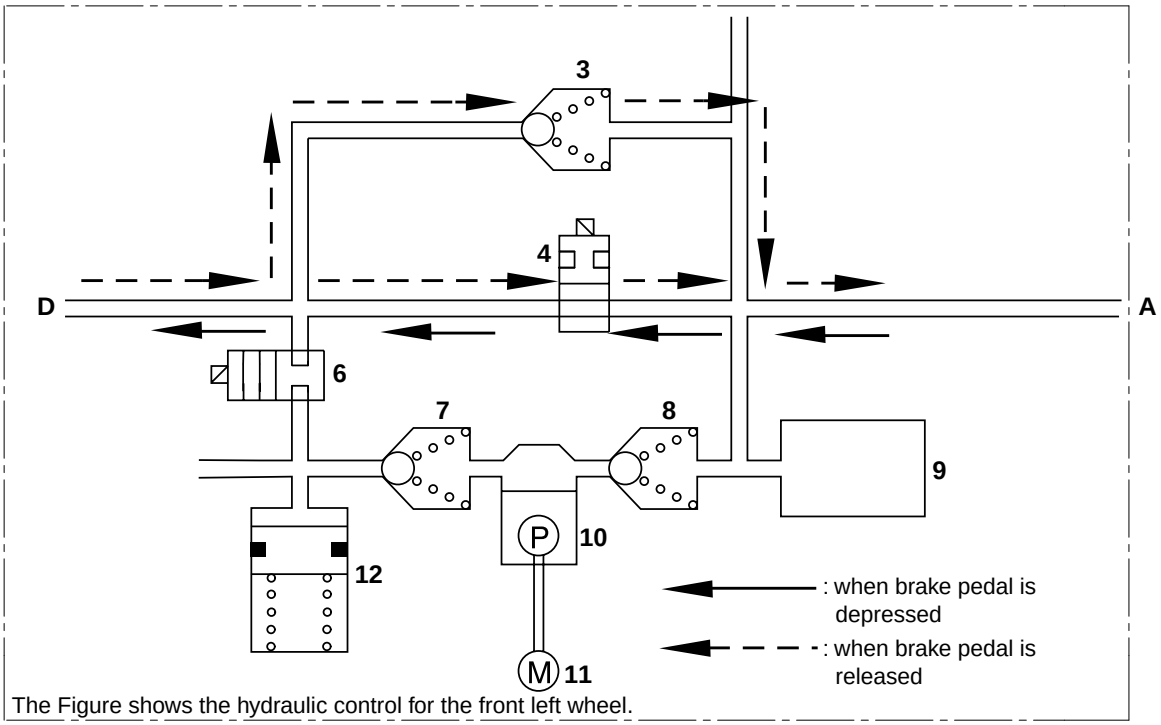
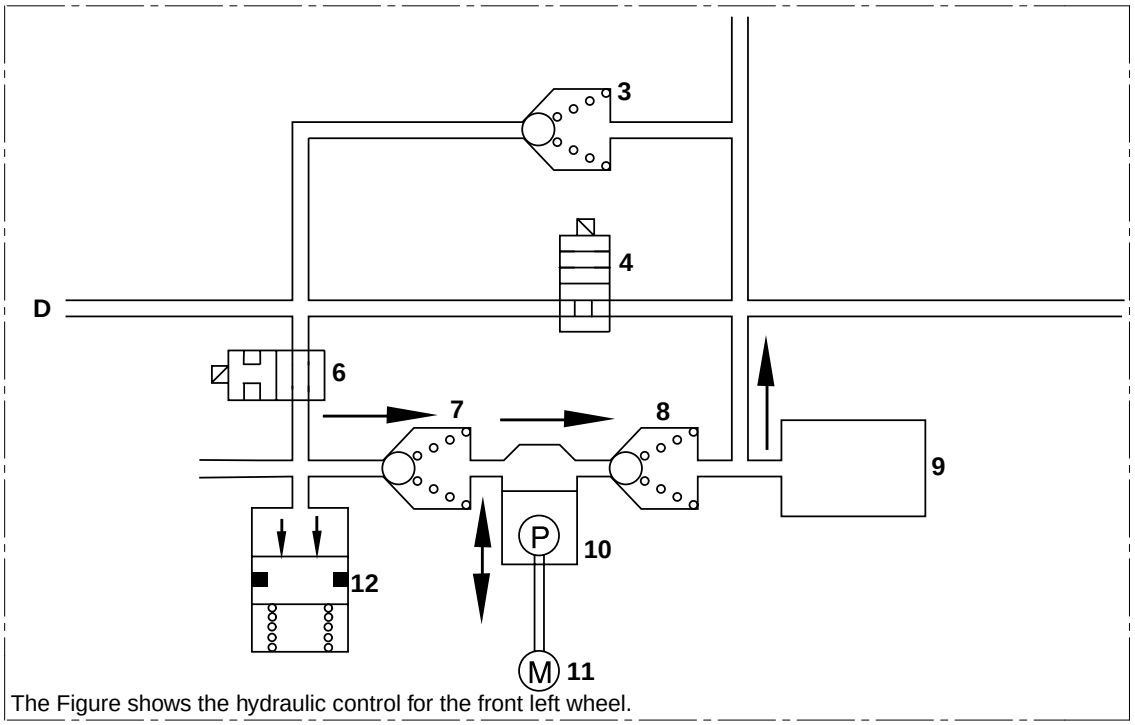
(2) Braking in normal conditions (Anti-lock brake system not activated)



Ⓟ36688

- In the conditions where the brake pedal is depressed but anti-lock brake system is not activated, no control signals are sent to the solenoid valve **6** (reducing pressure for front left wheel) and the solenoid valve **4** (holding pressure for front left wheel) in the hydraulic unit. Therefore, the solenoid valve **4** (holding pressure for front left wheel) is open and the solenoid valve **6** (reducing pressure for front left wheel) is closed.
- The brake fluid pressure **A** from the brake master cylinder is then fed to the wheel brake **D** through the solenoid valve **4** (holding pressure for front left wheel) without any modulation, braking the wheel.
- At that time, the brake fluid pressure is also applied to the damper **9** (front system), which is not activated with a normal brake fluid pressure.
- When the brake pedal is released, the brake fluid pressure **A** from the brake master cylinder is reduced. Therefore, the brake fluid pressure in the wheel brake **D** returns to the brake master cylinder through the solenoid valve **4** (holding pressure for front left wheel) and through the check valve **3** (front left wheel) whose ball is pressed off the seat by the pressure.

(3) When anti-lock brake system is activated (for reducing pressure)

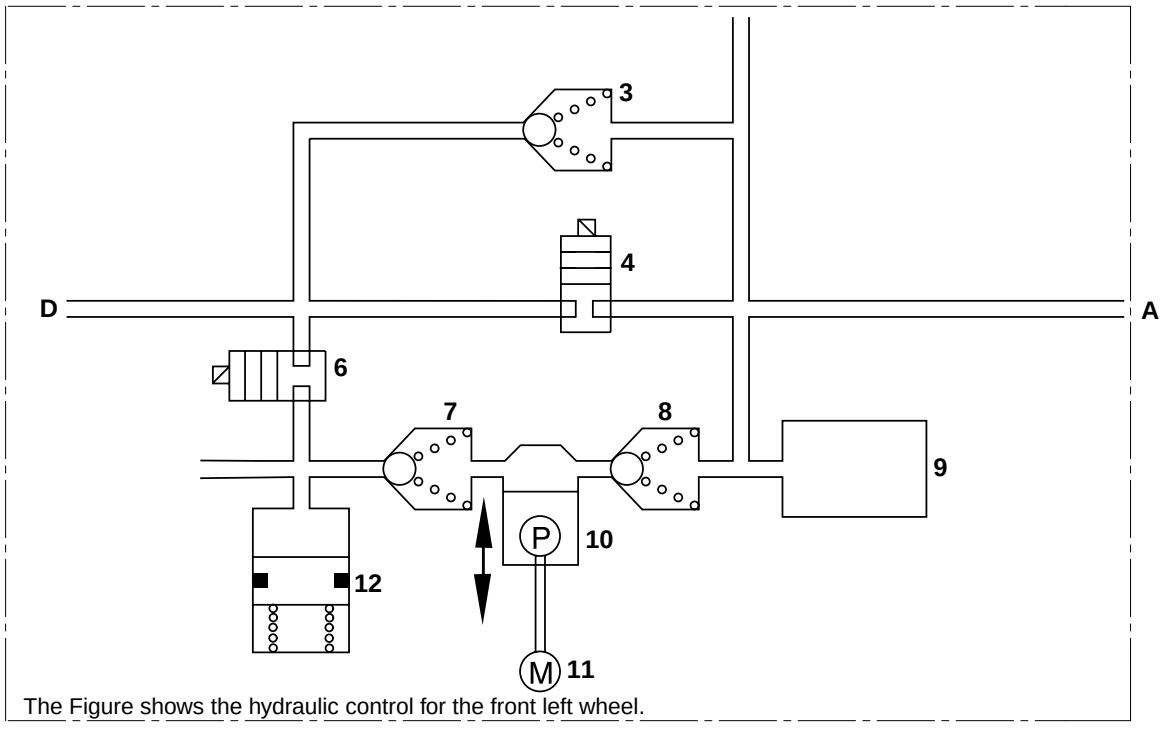


The Figure shows the hydraulic control for the front left wheel.

Ⓟ36689

- If the front left wheel shows signs of locking when the brake pedal is depressed, the electronic control unit sends the control signals to the solenoid valve **6** (reducing pressure for front left wheel) and the solenoid valve **4** (holding pressure for front left wheel). Then, the solenoid valve **6** (reducing pressure for front left wheel) opens and the solenoid valve **4** (holding pressure for front left wheel) closes.
- The brake fluid pressure in the wheel brake **D** is fed back into the reservoir **12** (front system) through the solenoid valve **6** (reducing pressure for front left wheel) and thereby it is reduced.
- Simultaneously with the control signals to the solenoid valve **6** (reducing pressure for front left wheel) and solenoid valve **4** (holding pressure for front left wheel), the electronic control unit also sends a control signal to the motor **11**, which operates the plunger pump **10** (front system). This causes the brake pressure in the reservoir to flow through the inlet valve **7** (front system) and outlet valve **8** (front system) into the damper **9** (front system).
- At this time, the check valve **3** (front left wheel) is closed by the brake fluid pressure **A** from the brake master cylinder. Accordingly, the brake fluid pressure is not fed from the brake master cylinder to the wheel brake.

(4) When anti-lock brake system is activated (for holding pressure)

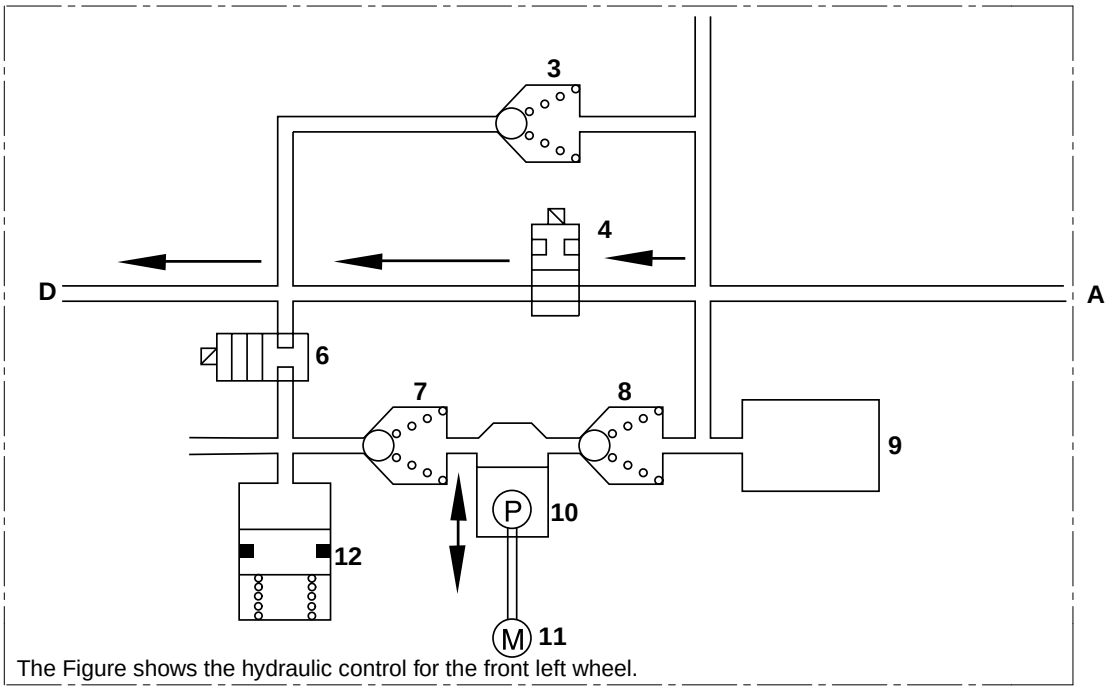


The Figure shows the hydraulic control for the front left wheel.

Ⓟ36690

If the brake fluid pressure **D** in the wheel brake should be maintained for sustained anti-lock brake system control, the electronic control unit sends the pressure holding signal to the solenoid valve **4** (holding pressure for front left wheel) and stops control signal to the solenoid valve **6** (reducing pressure for front left wheel). This causes both solenoid valve **4** (holding pressure for front left wheel) and solenoid valve **6** (reducing pressure for front left wheel) to close, thereby the brake fluid pressure being maintained.

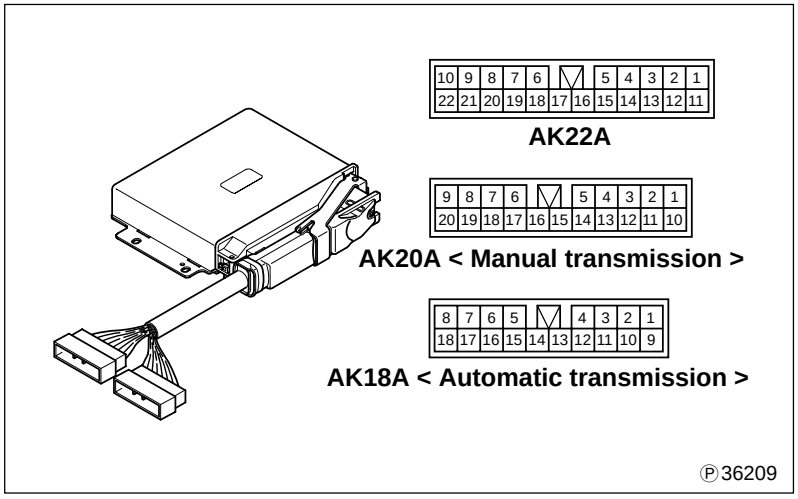
(5) When anti-lock brake system is activated (for increasing pressure)



The Figure shows the hydraulic control for the front left wheel.

Ⓟ36691

- If the brake fluid pressure **D** in the wheel brake should be increased, the electronic control unit stops sending control signals to the solenoid valve **4** (holding pressure for front left wheel) and solenoid valve **6** (reducing pressure for front left wheel) in the hydraulic unit.
- Then, the solenoid valve **4** (holding pressure for front left wheel) opens and the solenoid valve **6** (reducing pressure for front left wheel) closes. Namely, the same condition as where no anti-lock brake system control is provided brings about.
- At this time, the check valve **3** (front left wheel) is kept closed by the brake fluid pressure **A** from the brake master cylinder. Therefore, the brake fluid pressure **D** increased by the damper **9** (front system) is applied to the wheel brake irrespective of the brake fluid pressure in the brake master cylinder.



● **Electronic control unit**

This component calculates the wheel speed and estimates the vehicle speed based on signals sent from the wheel speed sensors. Based on the calculation results, it determines the degree of wheel lockup tendency, and sends brake fluid pressure control signals to the solenoid valves of the hydraulic unit to regulate brake fluid pressure accordingly.

The electronic control unit is equipped with a self-diagnosis function. Should an abnormality occur, the electronic control unit turns on the warning lamp on the instrument panel to indicate the system malfunction and deactivates the ABS control to set the brake system in normal condition (without anti-lock brake system control).

Periodic Inspection Procedures

(1) Periodic inspection of Anti-lock brake system

- Inspect the vehicle's Anti-lock brake system following the procedure below.
- If an abnormality is found in this inspection, further inspect the Anti-lock brake system using Multi-Use Tester II by referring to TROUBLESHOOTING section.
  P35E-21

- Inspection procedure
  ① With the vehicle stationary, press the brake pedal and inspect the hydraulic unit for fluid leaks.
  If fluid leaks from the hydraulic unit, replace the unit. If fluid leaks from the fluid pipe or connector, tighten the joint.
  ② Inspection using brake tester
  Check the braking force at each wheel with a brake tester by following the inspection procedure for ordinary vehicles.
  If an abnormality is found, inspect the wheel brake units, service brake system and hydraulic unit.
  ③ Drive the vehicle and check the operation of the Anti-lock brake system.
  - Conduct a test drive at an open area to ensure safety.
  - Conduct a test drive without cargo.

  Attach white tape **A** on the sides of tires, so that it is easy to observe the rotation of the front and rear wheels.
  - Turn the starter switch from the OFF position to the ON position, and make sure that the ABS warning lamp lights.
    Then, check that the ABS warning lamp turns off approximately two seconds after the starter switch is turned on.
  - Drive the vehicle at a speed of 20 to 30 km/h {12 to 19 mph}, and apply a sudden brake. Make sure that wheel lockup does not occur in any of the tires.

Tighten adjuster to extend wheel speed sensor **1**, and adjust clearance between the sensor and rotor **2**.

- Remove plug **4** located on the back side of back plate **3**.
- Mount adjuster in adjustment hole **A**, and tighten the adjuster.
- Wheel speed sensor **1** contacts the rotor before adjuster is completely tightened. Therefore, do not press shaft **B**, and tighten the adjuster until resistance is felt.
- Be sure to reinstall plug **4** after adjustment.

Inspection of Wheel Speed Sensor Signal Waveform Using Oscilloscope

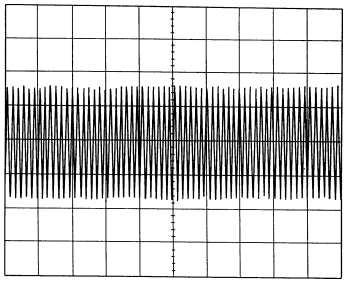
Inspect the rotor for dents using an oscilloscope, since the tester cannot be used for dent detection.

NOTE

Use an oscilloscope with a waveform recording function.

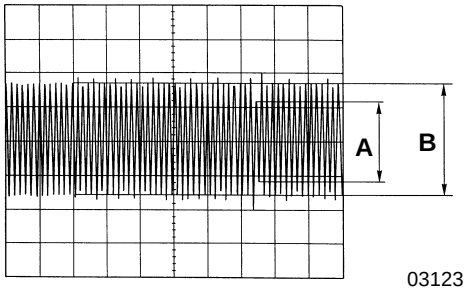
- Lift the wheel to be tested off the ground, and disconnect the connector at the wheel speed sensor.
- Connect the terminal of the oscilloscope to the terminal of the disconnected connector. Rotate the wheel at a constant speed. Check the waveform shown on the oscilloscope to check for dents on the rotor.

Normal waveform (no dent on rotor)



03122

Abnormal waveform (with dents on rotor)



03123

- Rotor dents are often made by the rotor press-fit on the hub end contacting the axle during installation of the hub and brake drum assembly on the axle. When installing the hub & brake drum assembly, pay close attention to prevent the rotor from contacting other parts.

A: Vmin (Minimum peak)
B: Vmean (Average of maximum peaks)

$$\frac{\text{Vmean} - \text{Vmin}}{\text{Vmean}} = 0.2 \text{ (20\% or lower)}$$

If more than 20%, replace the rotor.

Hydraulic Unit Operation Check

Operation check using Multi-Use Tester II

- Lift the vehicle using a jack and support it with rigid racks, or position the tires on brake tester rollers.

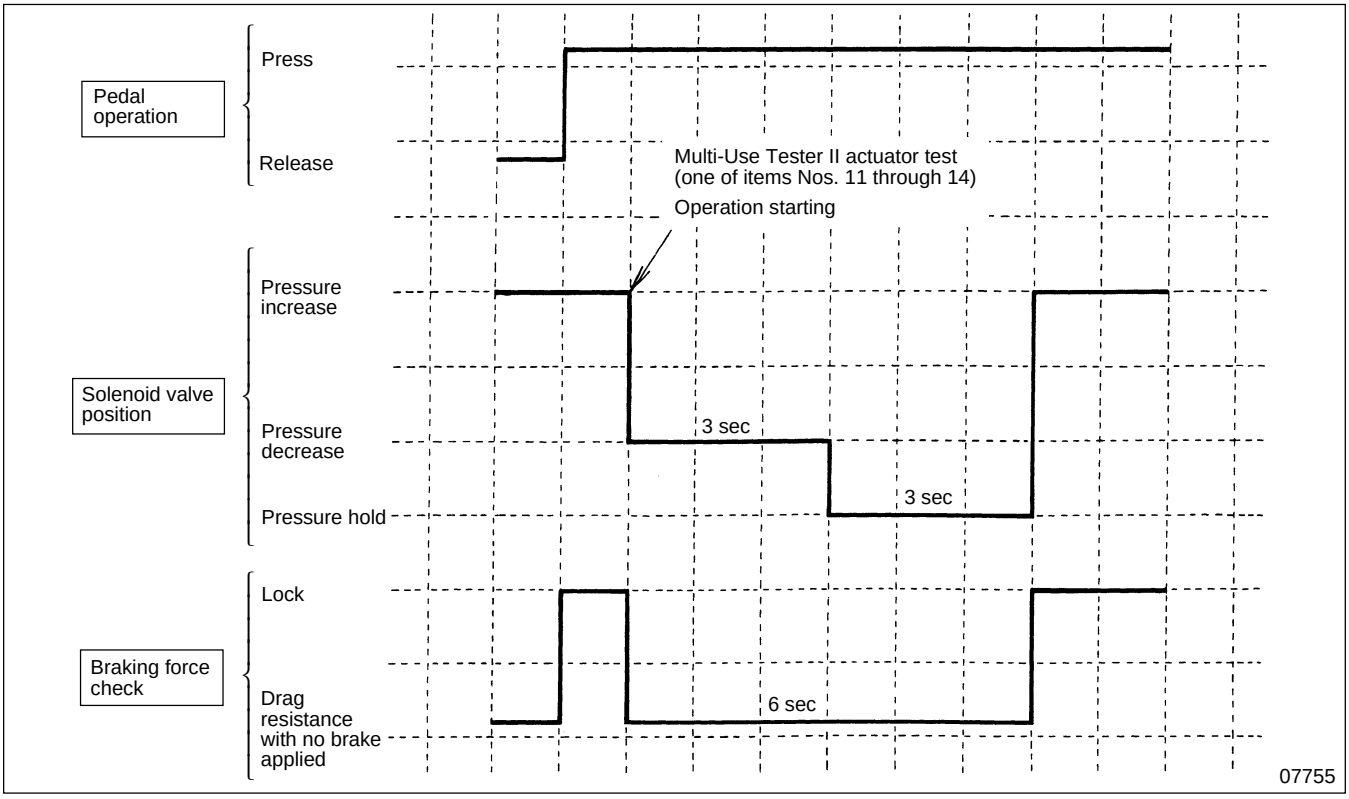
WARNING⚠

- **The brake tester rollers and tires must be dry during inspection.**
- **To test the front brakes, apply the parking brake. To test the rear brakes, place wheel chokes at the front tires to secure them in position.**

- Disengage the parking brake, and feel the drag resistance of the brake on each wheel.
  When using a brake tester, record the indicated drag resistance of the brake.
- Set the starter switch to the OFF position, then connect the Multi-Use Tester II.
- Set the testing equipment and system on the Multi-Use Tester II.
- After making sure that the transmission is in the neutral position, start the engine.

NOTE

- **When the engine is turned on, the anti-lock brake system switches to the Multi-Use Tester II mode and the anti-lock brake system warning lamp flashes.**
- **When the anti-lock brake system function is deactivated due to the electronic control unit fail-safe function, the actuator test cannot be performed with the Multi-Use Tester II.**



- If an abnormality is found during the inspection, take appropriate measures described in the following operating condition evaluation chart.

Operating condition evaluation chart

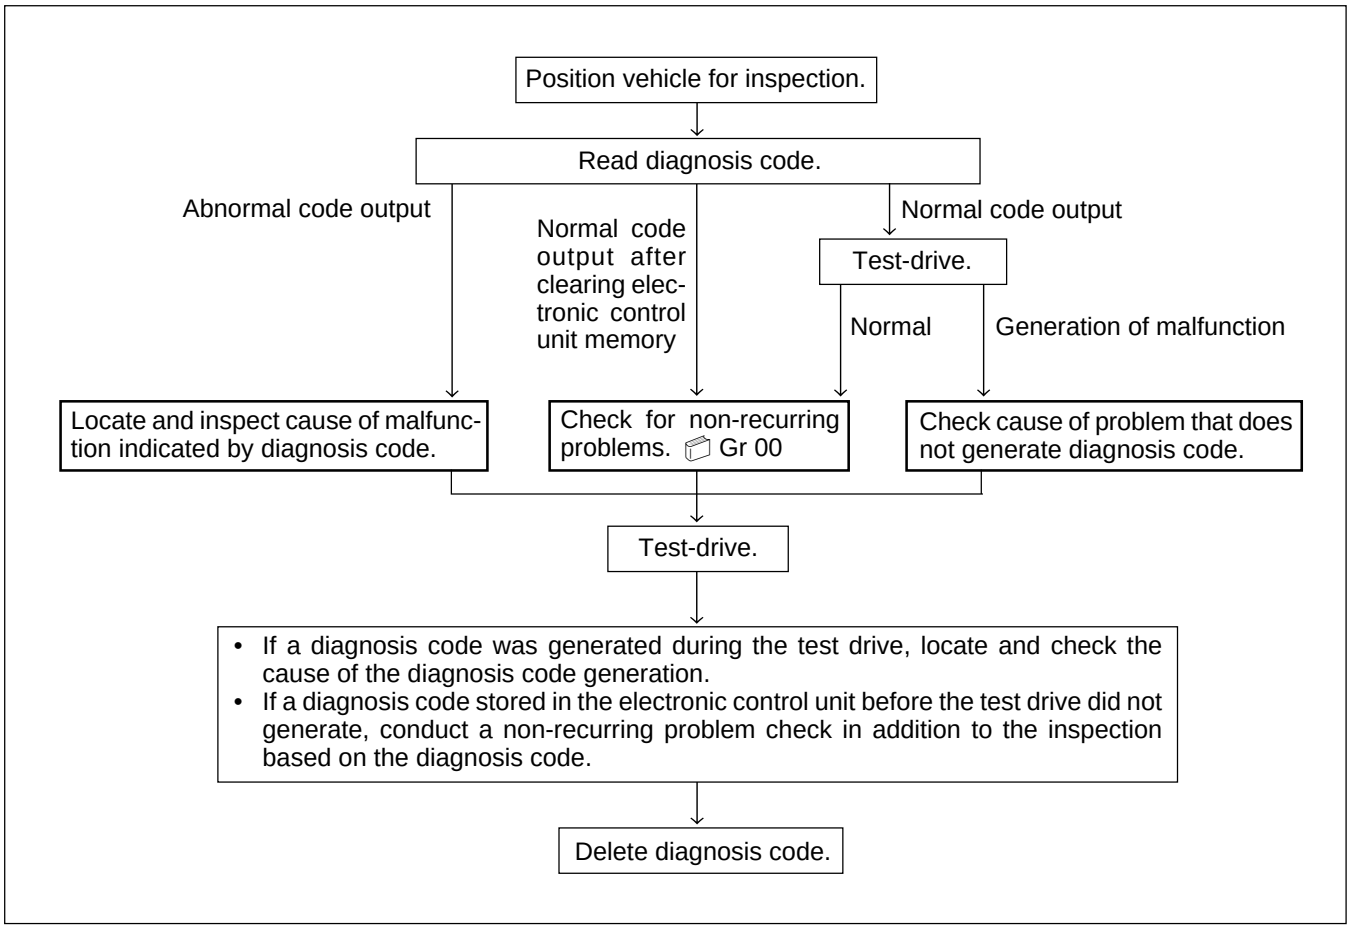
TROUBLESHOOTING

Troubleshooting Procedures

Inspection flow chart

The Multi-Use Tester II allows efficient inspection of the anti-lock brake system.
The types of system inspections can be roughly divided according to the malfunction condition and diagnosis code, as shown below.

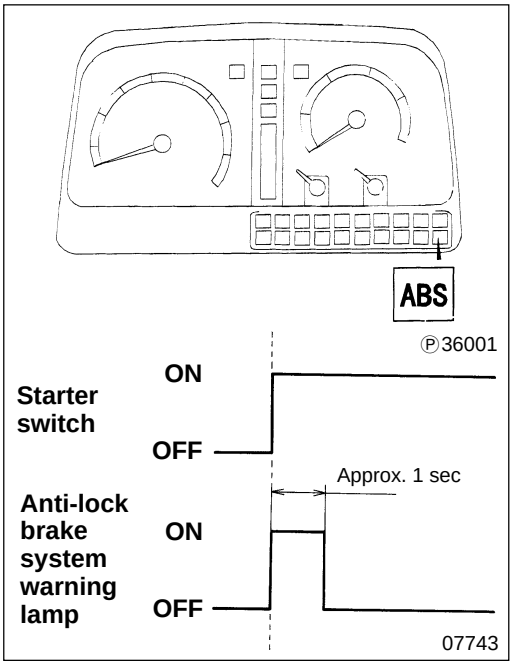
- Inspection based on individual malfunction diagnosis codes stored in the electronic control unit
- Inspection based on symptoms not indicated by diagnosis codes
- Correcting non-recurring problems



Cautions in malfunction diagnosis

- The anti-lock brake system uses electronic control to regulate the braking system. The following phenomena may occur during normal anti-lock brake system operation, but they do not denote a malfunction.

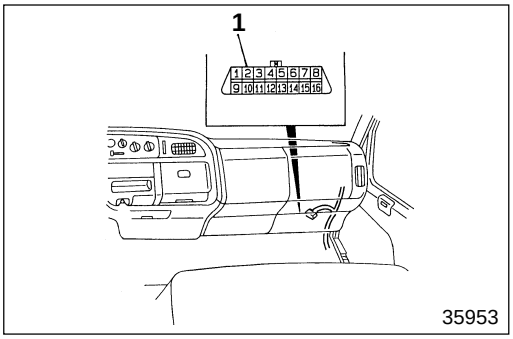
Phenomenon	Description
System checking sound	When the engine starts, a slight clunking sound may be generated in the left side of the frame near the cargo bed. This sound is produced by the system conducting an operation check, and does not denote a malfunction.
Anti-lock brake system operating sound	• Motor noise from the hydraulic unit (humming sound) • Noise generated as the brake pedal feel changes (grinding sound) • Noise from the chassis produced by repeated ON and OFF operations of the anti-lock brake system (wheels: short squeak, suspension: slight thud)
Anti-lock brake system operation effect (longer stopping distance)	On snow-covered surfaces and gravel roads, a vehicle equipped with anti-lock brake system may require a longer distance to come to a complete stop. Therefore, when driving on such road surfaces, reduce the speed sufficiently and drive carefully to minimize the use of brakes.



● **Inspection of anti-lock brake system warning lamp**

Check the anti-lock brake system warning lamp to make sure that the following operation turns on the lamp.

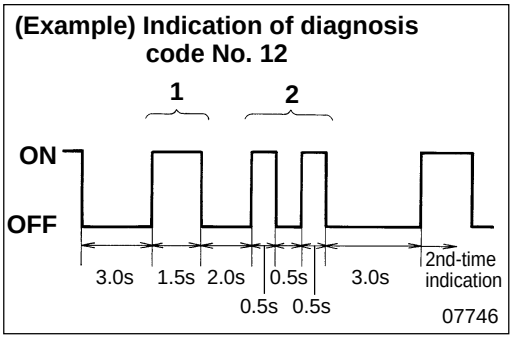
- Set the starter switch to the ON position, and check that the anti-lock brake system warning lamp lights for about 1 second and turns off.
- If the lamp does not light as described above, check diagnosis codes stored in the electronic control unit.



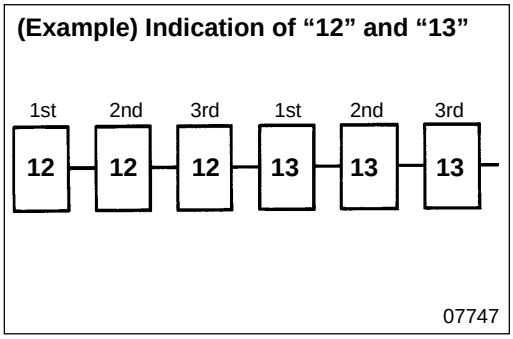
Diagnosis code indication

● **Without Multi-Use Tester II**

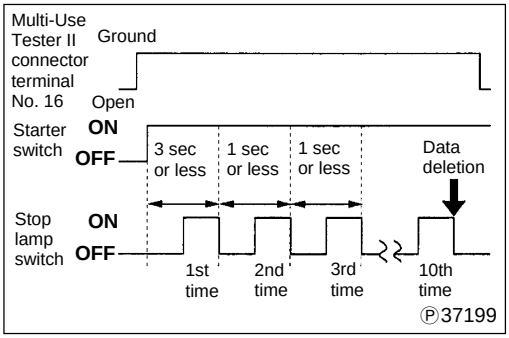
- With the vehicle stationary, ground terminal No. 16 of Multi-Use Tester II connector **1**, then turn the starter switch to the ON position. The anti-lock brake system warning lamp will flash to indicate a diagnosis code.
- The anti-lock brake system warning lamp starts flashing 3.0 seconds after the starter switch is turned ON. The flashing pattern of the warning lamp indicates a diagnosis code.



- A diagnosis code is indicated in the following manner.
  - To indicate the tens digit (left digit), the lamp remains ON for 1.5 seconds, then remains OFF for 0.5 seconds. To indicate the ones digit (right digit), the lamp remains ON for 0.5 second, then remains OFF for 0.5 second.
  - Each diagnosis code is indicated three consecutive times. When there is no other diagnosis code to indicate, the lamp repeats the diagnosis code indication from the beginning.
  - When there is no diagnosis code stored in the memory (normal condition), the anti-lock brake system warning lamp repeats On/Off in 0.25-second intervals.



- When two or more diagnosis codes are stored in the electronic control unit.



● **Deletion of diagnosis codes**

Connect terminal No. 16 of the Multi-Use Tester II connector to the chassis for grounding. Turn on the starter switch, and depress the brake pedal within 3 seconds and turn On and Off the stop lamp switch ten times in intervals of 1 second or less. This erases diagnosis codes from the memory.

● **Completion of diagnosis code check**

The diagnosis code check completes when diagnosis codes are erased from the electronic control unit of terminal No. 16 of the Multi-Use Tester II connector is disconnected.

NOTE

The diagnosis code check also ends when the vehicle moves from a stationary condition during the diagnosis code check.

Connecting the Multi-Use Tester II
- Turn the starter switch to the LOCK position.
- Connect the b MUT Communication Harness to the a Multi-Use Tester II, and insert the c ROM Pack.
- Plug connector **A** into the cigarette lighter socket.
- Fit connector **C** onto MUT connector **B** (16 pin) in the relay box.

NOTE

Instructions for operation of the Multi-Use Tester II are given in the separate Multi-Use Tester II Reference Manual.

Current diagnosis codes
- Turn the starter switch to the ON position.
- Determine the fault location(s) in accordance with the Multi-Use Tester II diagnosis code(s).

Past diagnosis codes
- Turn the starter switch to the ON position.
- Determine the fault location(s) in accordance with the past Multi-Use Tester II diagnosis code(s).

Diagnosis code erasure
- Turn the starter switch to the ON position.
- Using the Multi-Use Tester II, erase all diagnosis codes stored in the control unit.

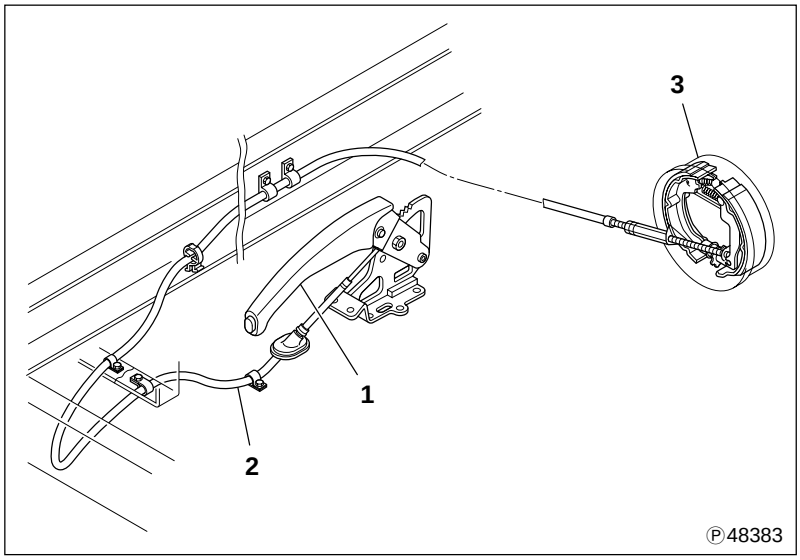
SPECIFICATIONS

Item		Specifications
Brake	Type	Propeller shaft internal expanding type brake
	Operation type	Mechanical cable type
Parking brake assembly	Type	Duo-servo type
	Inner diameter of drum mm {in.}	ø190 {7.48}
	Lining width × Thickness mm {in.}	45×4.0 {1.77×0.16}

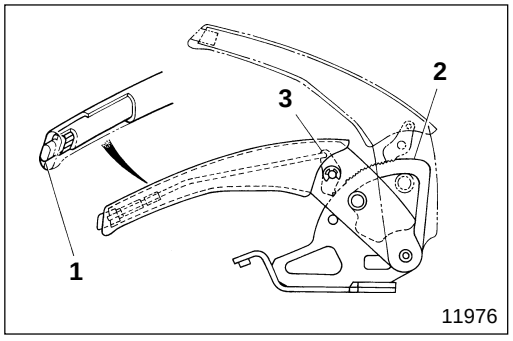
STRUCTURE AND OPERATION

1. Parking Brake Control



1 Parking brake lever
2 Parking brake cable
3 Parking brake assembly

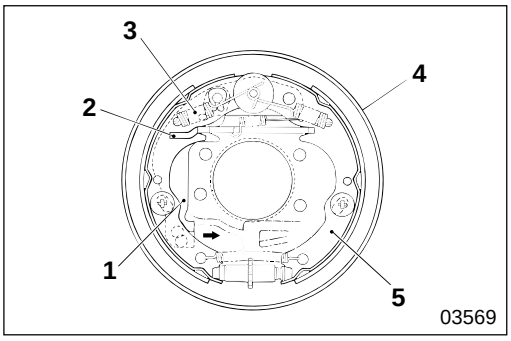
2. Parking Brake Lever



1 Release rod knob
2 Lever bracket
3 Locking latch

The parking brake has a built-in locking mechanism that prevents inadvertent release of the brake.
To release locking, push release rod knob **1** which will disengage from the serration of lever bracket **2** and the tooth of locking latch **3** freeing the parking brake lever and allowing it to return.

3. Parking Brake Assembly



1 Parking lever
2 Strut
3 Shoe return spring
4 Backing plate
5 Shoe and lining assembly

- Pulling the parking brake ratchet bar pulls the parking brake cable, which in turn pulls parking brake lever **1** installed in the parking brake body, operating shoe and lining assembly **5**.
- Activation of parking lever **1** expands one shoe and lining assembly **5** via strut **2**, the parking lever itself expands the other shoe and lining assembly. Therefore, both shoe and lining assemblies function as leading shoes.
- When the ratchet bar (parking lever) is returned, the repercussive force of shoe return spring **3** releases the brake.

1. Adjustment of Parking Brake Shoe Clearance and Ratchet Bar Pulling Stroke

Service standards

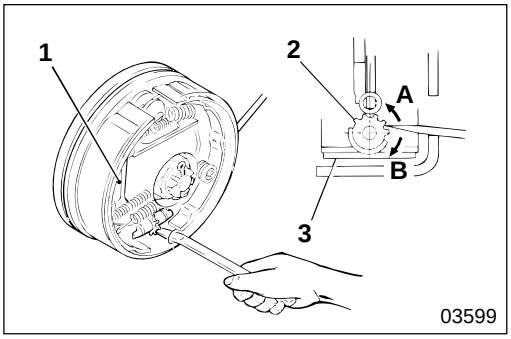
Unit : mm {in.}

Location	Maintenance item	Standard value	Limit	Remedy
—	Brake shoe clearance	0.2 to 0.25 {0.0079 to 0.0098}	—	Adjust
4	Ratchet bar pulling stroke (Operating force : 490 N {110 lbf, 50 kgf})	7 to 10 notches	—	Adjust

Ⓣ Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
6	Lock nut	19 to 27 {14 to 20, 1.9 to 2.8}	—

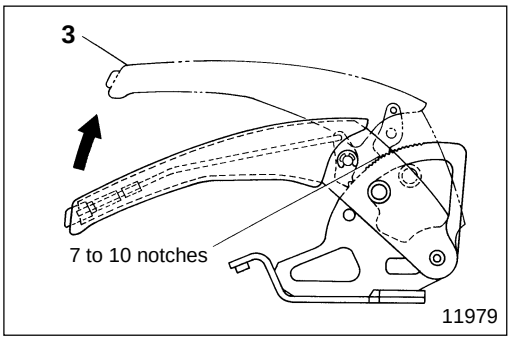


(1) Shoe clearance

When parking lever **1** is released, turn adjuster **2** in the expansion direction, using a screwdriver inserted through the shoe adjusting hole of the parking brake drum, and return 8 to 10 notches from the position where shoe **3** is in close contact with the drum. Then, the shoe clearance will be the standard value.

A : Contraction

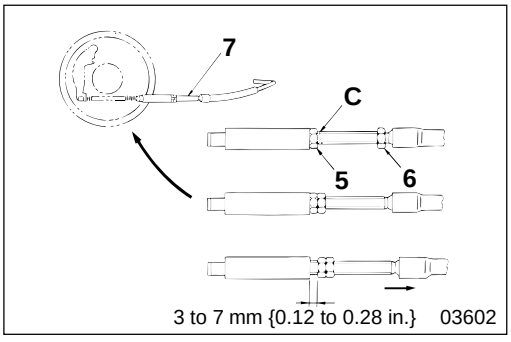
B : Expansion



(2) Ratchet bar pulling stroke

Adjust the adjusting nut of the parking brake cable so that the ratchet bar pulling stroke is the standard value when parking brake ratchet bar **4** is pulled from the released position by an operating force of 295 N {66 lbf, 30 kgf}.

Operate ratchet bar two or three times after adjusting to verify the pulling stroke, to make sure that the parking brake is operating properly and that the parking brake drum does not drag when the parking brake is released.



[Adjustment]

- Tighten adjusting nut **5** until mark **C** can be seen.
- Tighten lock nut **6** to the position of adjusting nut **5**.
- Tighten lock nut **6** at specified torque.
- Check clearance when the outer cable of parking brake cable **7** is pulled by an operating force of 59 to 98 N {13 to 22 ft.lbs, 6 to 10 kgf·m}.

STRUCTURE AND OPERATION

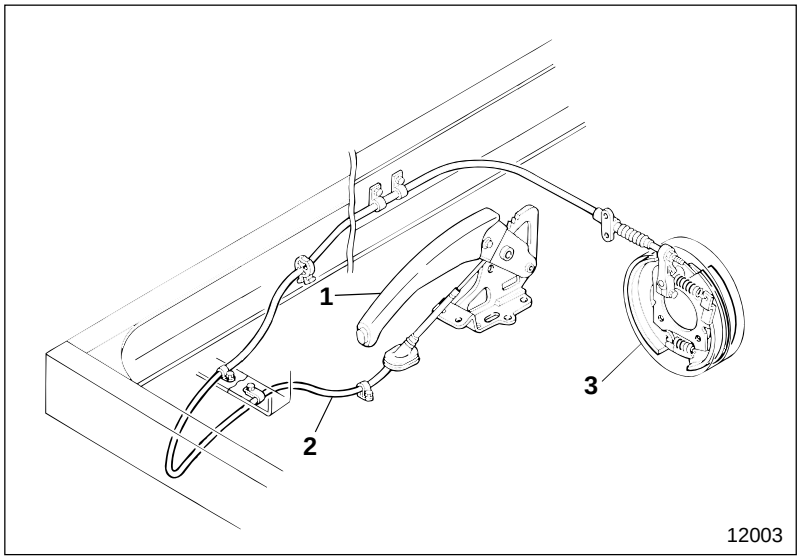
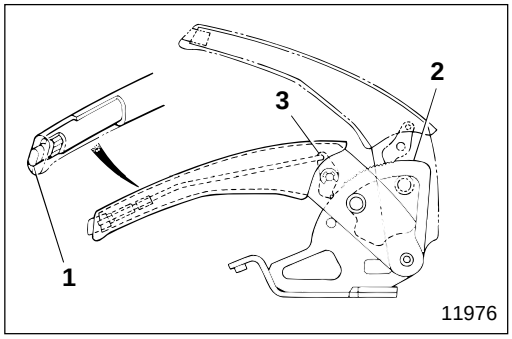
1. Parking Brake Control



1 Parking brake lever
2 Parking brake cable
3 Parking brake assembly

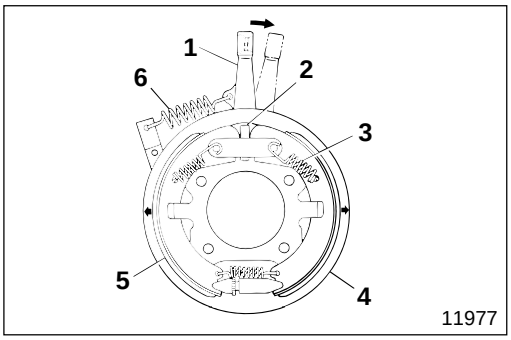
2. Parking Brake Lever



1 Release rod knob
2 Lever bracket
3 Locking latch

The parking brake has a built-in locking mechanism that prevents inadvertent release of the brake.
To release locking, push release rod knob **1** which will disengage from the serration of lever bracket **2** and the tooth of locking latch **3** freeing the parking brake lever and allowing it to return.

3. Parking Brake Assembly



1 Camshaft lever
2 Camshaft
3 Shoe return spring
4 Dust cover or support plate and cover assembly
5 Shoe and lining assembly
6 Camshaft lever return spring

Pulling the parking brake lever pulls the parking brake cable, which in turn pulls camshaft lever **1**. At the same time, camshaft **2** rotates in conjunction with the camshaft lever, and expands shoe and lining assembly **5** making it press against the brake drum. This frictional force locks the propeller shaft that is connected to the drum. When the brake lever is released, the repercussive force of shoe return spring **3** releases the brake.

Shifting lock lever **A** from lock position **B** to release position **C** produces high tilt **D**, and turning telescopic lever **E** (counterclockwise) from lock position **F** to release position **G** allows telescopic movement **H**. In this way, the structure of steering column subassembly **2** can be adjusted for optimum driving position.

- In vehicles equipped with hydraulic booster brake, power steering oil pump **2** hydraulic pressure is also used for brake booster (hydraulic booster) **3** by the power steering system. Although the power steering pump is shared by both the power steering system and the brake system, the spool valve inside brake booster (hydraulic booster) ensures that power steering booster **4** and brake booster (hydraulic booster) operate without interfering with each other.

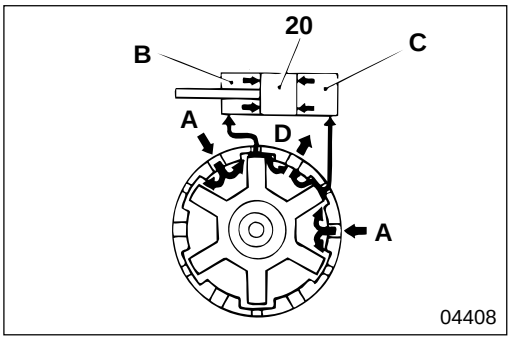
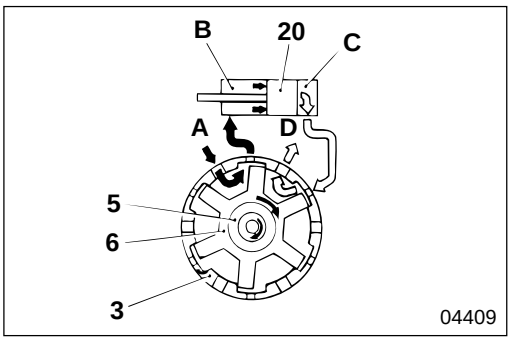
The rotary valve is the central part of the power steering booster. The torsion bar allows the steering reaction force and valve return to operate lightly and smoothly at low speed, and ensures stable steering feel even at high speed.



● **Straight-ahead operation**

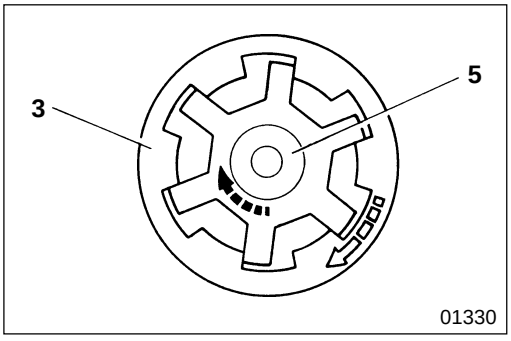
Piston **20** is in the neutral position as chambers **B** and **C** of the piston are under equal pressure.

A : From oil pump
D : To oil tank



● **Steering operation**

Turning the steering wheel rotates stub shaft **5**, causing rotor **6** to close the fluid feed passage to cylinder chamber **C**. This produces a pressure difference between cylinder chambers **B**, **C**, which causes piston **20** to move, and facilitates rotation of worm shaft **3**.



If the hydraulic circuit fails

The safety mechanism allows the vehicle to be steered manually, when the rotating force of stub shaft **5** alone directly turns worm shaft **3**, transmitting the steering force.

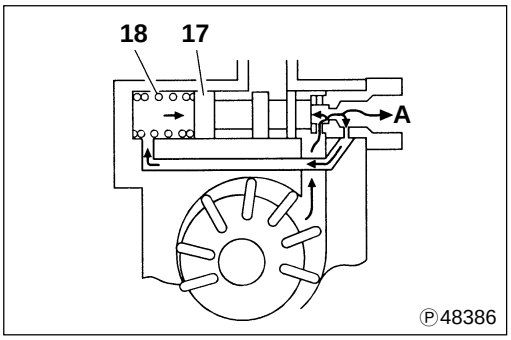
- The power steering oil pump produces hydraulic pressure for the power steering system. Inside the pump, vanes are installed in the grooves of cartridge assembly **13**, and driving power is transmitted from the engine by means of gears.
- The power steering oil pump is comprised of an oil pump which discharges oil, a flow control valve that regulates the flow rate, and a relief valve which limits the pressure increase.
- Flow control valve assembly **17** maintains a constant flow of oil to the power steering booster when the steering wheel is operated.
  When the steering wheel is not operated, the relief valve built in the flow control valve assembly prevents the oil pressure from increasing inside the pump.

● Front Control Valve Assembly



(1) Front control valve assembly

< When pump is rotating at low speed >

Because the force of flow control spring **18** is stronger than the oil pressure applied to front control valve assembly **17**, the flow control assembly remains in the same position, thus sending oil to the power steering booster.

A : To power steering booster

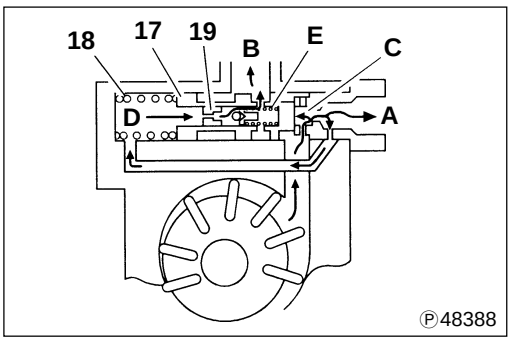
B : To pump section



(2) Relief valve section

When the steering wheel is not operated, the pressure of oil between the power steering oil pump and power steering booster increases because the pump is rotating. In this condition, oil pressure is applied to passage **C** and chamber **D**. The oil pressure compresses relief valve spring **E**, thus moving relief valve **19** and returning oil to the pump section.

This reduces the oil pressure build up in the power steering pump.

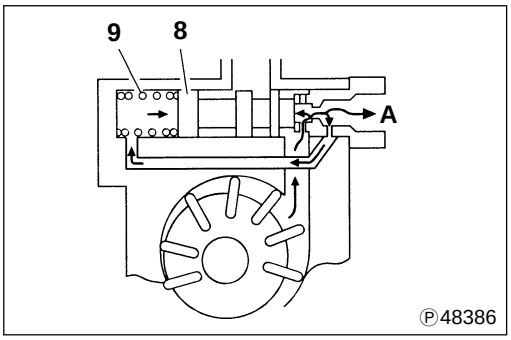
● Flow Control Valve Assembly

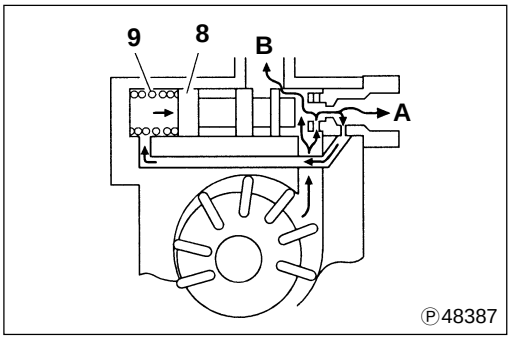


(1) Front control valve assembly

< When pump is rotating at low speed >

Because the force of flow control spring **9** is stronger than the oil pressure applied to front control valve assembly **8**, the flow control assembly remains in the same position, thus sending oil to the power steering booster.

A : To power steering booster

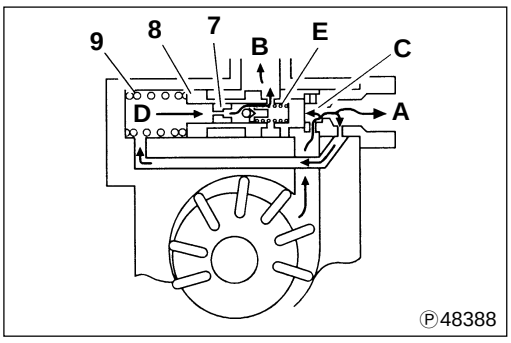


< When pump is operating at medium or high speed >

Increased rotating speed of the power steering oil pump causes the amount of oil that passes through the pump to exceed a certain level. When this happens, the oil pressure compresses flow control spring **9**, thus moving flow control assembly **8** and returning part of oil to the pump section. This results in the same amount of oil flow to the power steering booster as when the pump rotates at slow speed.

A : To power steering booster

B : To pump section



(2) Relief valve section

When the steering wheel is not operated, the pressure of oil between the power steering oil pump and power steering booster increases because the pump is rotating. In this condition, oil pressure is applied to passage **C** and chamber **D**. The oil pressure compresses relief valve spring **E**, thus moving relief valve **7** and returning oil to the pump section.

This reduces the oil pressure build up in the power steering pump.

- Jack up the front wheels.
- Loosen oil pipe **2** connected to power steering booster **1**.
- Turn the steering wheel fully left and right repeatedly, and drain the fluid from power steering booster **1**.
- After draining the fluid, tighten oil pipe **2** at specified torque.

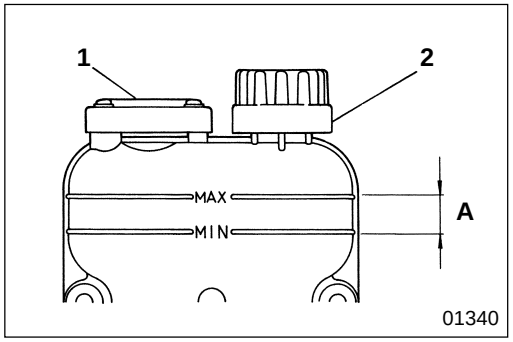
2. Bleeding of Power Steering System

Fluid

Location	Points of application	Specified fluid	Quantity
1	Power steering oil tank	Automatic transmission fluid (DEXRON or DEXRON II type)	Between the "MAX" and "MIN" levels in the power steering oil tank

WARNING

Because the brake booster (hydraulic booster) uses power steering fluid, do not let other fluids such as brake fluid, etc. get mixed with the power steering fluid inside the power steering oil tank.



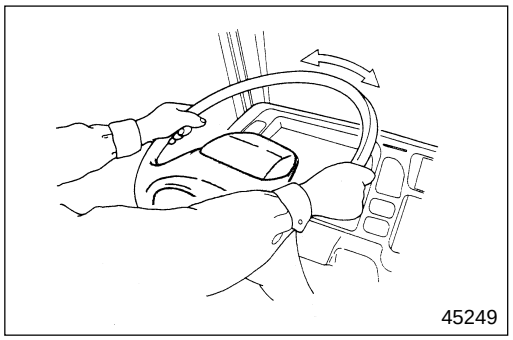
- Supply fluid into power steering oil tank **1** up to filler cap **2**.
- With the engine stopped, jack up the front wheels and turn the steering wheel fully left and right repeatedly. When the fluid level has dropped, add fluid to maintain the fluid level within range **A**.
- Start the engine and letting it idle, turn the steering wheel fully left and right repeatedly. When the fluid level has dropped, add fluid to maintain the fluid level within range **A**. Repeat these steps until the fluid level does not drop.
- Depress the brake pedal fully several times repeatedly, until as in the case of the steering wheel, the fluid level does not drop anymore. (The steering wheel at such time does not need to be operated)
- If there is an abnormal noise, air is still in the system. Turn the steering wheel several times, next depress the brake pedal several times to raise the fluid temperature to approximately 60 to 80°C {140 to 176°F}, then stop the engine and wait for approximately five minutes.
- Lower the front wheels and turn the steering wheel several times to make sure there is no abnormal noise.
- With the engine stopped, depress the brake pedal several times, activate the brake booster (hydraulic booster) emergency pump and bleed air.
- When there is no abnormal noise after the above procedure has been performed, bleeding is completed. Check oil tank **1** fluid level, and pipe and hose connections for fluid leakage.
- After bleeding is completed, inspect brake booster (hydraulic booster) performance (input and output characteristics). Gr 35A

3. Steering Wheel Play

Service standards

Unit : mm {in.}

Location	Maintenance item	Standard value	Limit	Remedy
—	Steering wheel play (Measure at the outer circumference of steering wheel)	10 to 40 {0.39 to 1.57}	—	Adjust

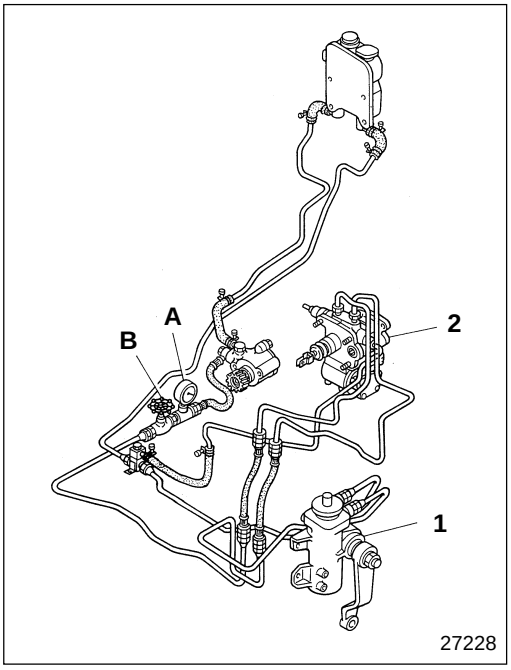


Point the wheels directly forward and gently turn the steering wheel left and right and measure the outer circumference play. If the play deviates from the standard value, adjust tightening points and power steering booster backlash. P37-31

4. Performance Verification Test of Power Steering System

Service standards

Location	Maintenance item		Standard value	Limit	Remedy
—	Steering system fluid pressure (With hands off steering wheel)		490 kPa {71 psi, 5 kgf/cm²}	—	Repair
—	Relief set pressure (Measure with engine speed at 1000 to 1500 rpm and the stop valve closed)	FH211	12.3 MPa {1780 psi, 125 kgf/cm²}	Maximum +490 kPa {71 psi, 5 kgf/cm²} Minimum –196 kPa {28 psi, 2 kgf/cm²}	Disassembly of power steering oil pump
		FH210	11.8 MPa {1706 psi, 120 kgf/cm²}		



Verify that power steering booster **1** and the power steering oil pump are operating properly by testing the following items.

NOTE

If the fluid pressure is higher than 490 kPa {71 psi, 5 kgf/cm²} with engine idling and the steering wheel free, inspect power steering booster 1, brake booster (hydraulic booster) 2 and the fluid circuit for clogging.

Test item	Test procedure	Assembly standards
Verification of smooth operation	Jack up the front wheels and turn steering wheel fully left and right	Smooth operation throughout test
Measurement conditions	• Install oil pressure gauge **A** capable of measuring above 14.7 MPa {2130 psi, 150 kgf/cm²} and stop valve **B**, then bleed air • With engine idling, turn steering wheel left and right several times to raise fluid temperature to 50 to 60°C {122 to 140°F} • With the engine idling, open stop valve **B**	
Measurement of fluid pressure	• Measure fluid pressure with hands off steering wheel	490 kPa {71 psi, 5 kgf/cm²}
Measurement of relief pressure	• Gradually increase engine speed and maintain it at 1000 to 1500 rpm, and close stop valve **B** to measure maximum fluid pressure • Do not keep stop valve **B** closed for more than fifteen seconds	Relief set pressure 11.8 MPa {1706 psi, 120 kgf/cm²} < FH210 > 12.3 MPa {1780 psi, 125 kgf/cm²} < FH211 >

Lubricant

Location	Points of application	Specified lubricant	Quantity

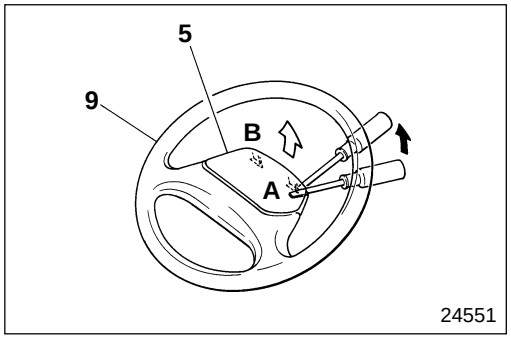
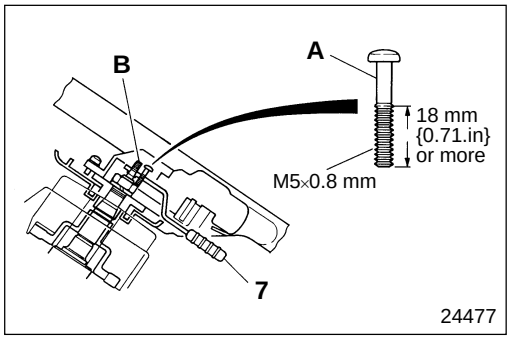
◆ Service procedure



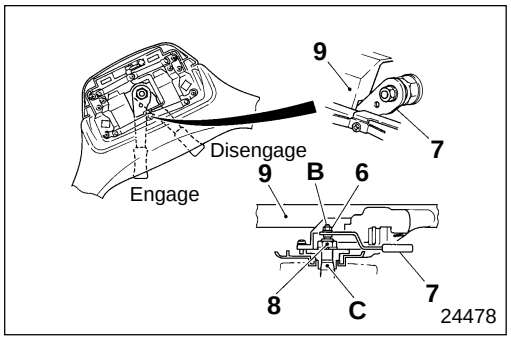
5 Removal of horn pad

- Insert a flat-tip screwdriver into the space between steering wheel assembly **9** and shoulder sections **A**, **B** of horn pad **5**, and disengage the latch by prying open the horn pad with the screwdriver until a clicking sound is produced.
- Insert a finger into the space behind horn pad **5** and remove the horn pad.



7 Telescopic lever

[Removal]
Secure screw **A** (M5×0.8 mm) in tapped hole in telescopic lever **7** and remove telescopic lever from telescopic shaft **B**.



[Installation]

- Make adjustment so that telescopic lever **7** positioned at the designated location applies the specified torque on telescopic shaft **B**.

CAUTION ⚠
Be careful not to damage the threads on the tip of telescopic shaft B.

C : Telescopic shaft assembly

Start procedure

Install steering wheel assembly **9**. Using a long socket wrench, tighten nut **8** at specified torque 39 to 49 N·m {29 to 36 ft.lbs, 4 to 5 kgf·m}

Rotate telescopic shaft **B** counterclockwise with your fingers and check for looseness

Looseness found

No looseeness

Using a flat-blade screwdriver turn telescopic shaft **B** clockwise and drive it in until it hits lightly with a “clunk”, but do not turn it any further

CAUTION

Be careful not to over tighten or you will crush the end of the telescopic shaft, requiring replacement of telescopic shaft assembly C

Install telescopic lever **7** at a location that allows easy tightening, then tighten nut **6** until the telescopic lever will not slip

Tighten telescopic shaft **B** at operating torque 6.9 to 7.8 N·m {5.1 to 5.8 ft.lbs, 0.7 to 0.8 kgf·m}. (Tighten telescopic bar **7** at torque 69 to 78 N {15 to 18 lbf, 7 to 8 kgf} at 100 mm {3.94 in.} from the center of steering wheel assembly **9**

To maintain lock, hold telescopic lever **7** clockwise, then loosen and remove lock nut **6**

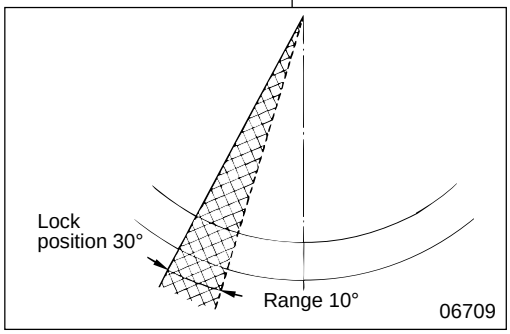
Remove telescopic lever **7**

NOTE

Remove telescopic lever 7 following the description under [Removal], taking care not to loosen telescopic shaft B.

Set telescopic lever **7** to specified lock position (within **10°** before the position at which telescopic lever contacts steering wheel assembly **9**).

Tighten nut **6** at specified torque 8.8 to 9.8 N·m {6.5 to 7.2 ft.lbs, 0.9 to 1.0 kgf·m}



When telescopic lever **7** is released, and telescopic shaft **B** is retightened at operating torque 6.9 to 7.8 N·m {5.1 to 5.8 ft.lbs, 0.7 to 0.8 kgf·m}, the telescopic lever should lock in the 10° range this side of specified lock position 30°

Out of the range

Within the range

Jiggle steering wheel assembly **9** up and down and check for looseness

Looseness found

No looseness

Remove nut **6**

Procedure is completed

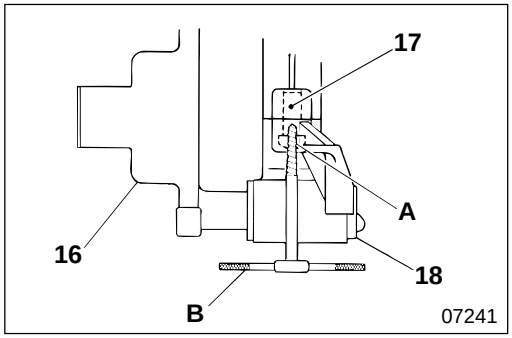
Remove telescopic lever **7**

CAUTION

Be sure not to operate telescopic shaft B while steering wheel assembly 9 is removed.

NOTE

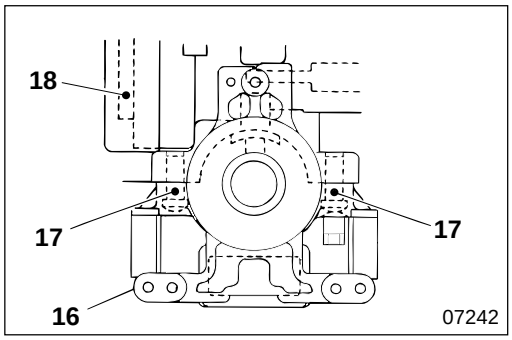
Be sure to assemble telescopic lever 7 only after steering wheel assembly 9 has been installed.



17 **18** **Head cutting bolt, starter switch**

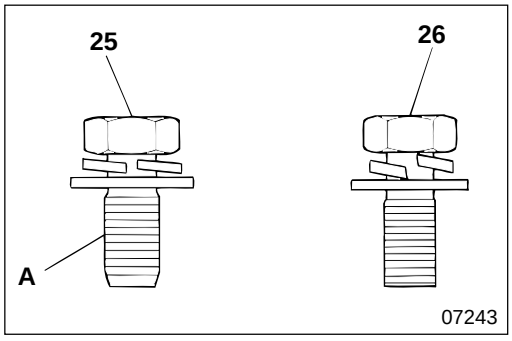
[Removal]

- After removing bracket **16**, drill a ø5.5 to 6.0 mm {0.22 to 0.24 in.} hole 10 to 15 mm {0.39 to 0.59 in.} deep in surface **A** of head cutting bolt **17** for mounting starter switch **18**.
- Screw in screw extractor **B** counterclockwise, then remove head cutting bolt **17**.



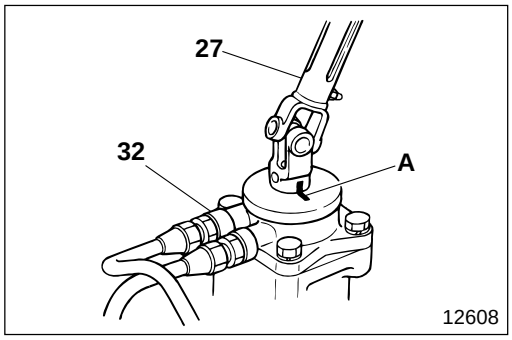
[Installation]

- With new head cutting bolt **17**, tighten starter switch **18** at specified torque to cut the head off the bolt.
- After installing bracket **16**, verify operation of the steering lock function of starter switch **18**.



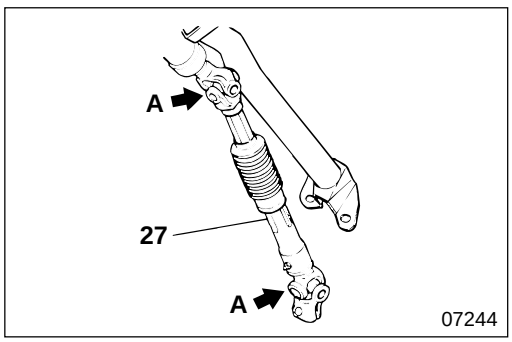
25 **26** **Installation of bolt**

- Bolts **25** and **26**, differ in shape. Do not mix them up when installing.
- Thread area **A** of bolt **25** is elliptical to facilitate grounding of the horn circuit.



27 **32** **Removal and installation of steering column subassembly, and power steering booster**

Before removing steering column subassembly **27** or power steering booster **32**, be sure to make alignment mark **A**.



27 **Steering column subassembly**

When the spline of steering column subassembly **27** has been disconnected, align marks **A** on the yokes to face the same direction.

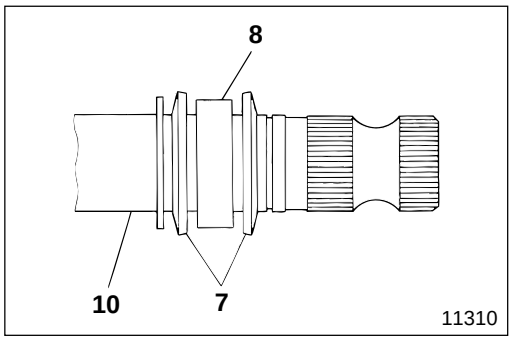
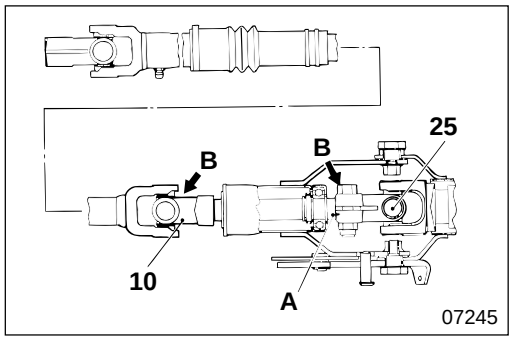
◆ Service procedure



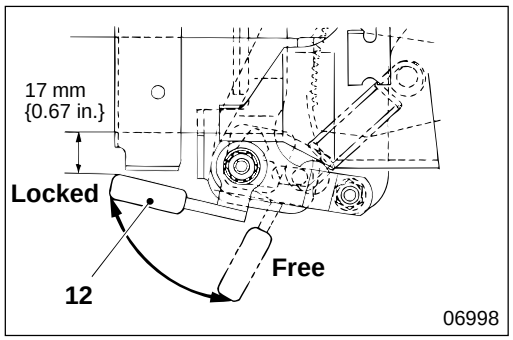
7 **Installation of stopper**

Install stoppers **7** on steering shaft assembly **10** in the direction as illustrated so that they straddle bearing spacer **8**.



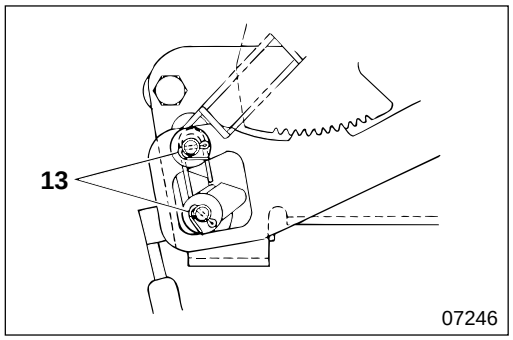
10 **Steering shaft assembly**

- Before removing steering shaft assembly **10**, be sure to make alignment mark **A**.
- Install the steering shaft with direction **B** of the telescopic shaft assembly **25** yoke and steering shaft assembly **10** yoke aligned or at phase angle of 90°.



12 **Installation of lock lever**

- Install lock lever **12** so it is within the working angle when locked.
- After installing lock lever **12**, make sure that the lever operates smoothly (operating force less than 49 N {11 lbf, 5 kgf}). With the lever free, make sure that high tilt operates smoothly.



13 **Installation of split pin**

Bend split pin **13** to face outwards as illustrated.

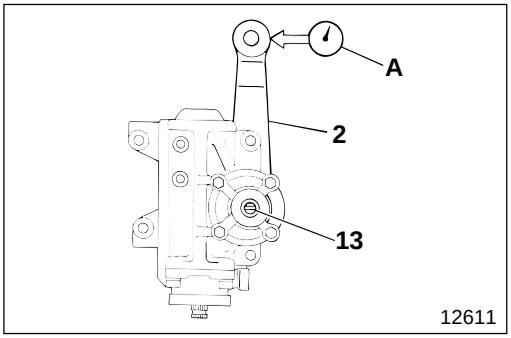
◆ Service procedure

● Work before disassembly

Move pitman arm **2**, and align slit **A** of the V-groove of sector shaft **14** to the center of body **49** so that the gears are in neutral position.

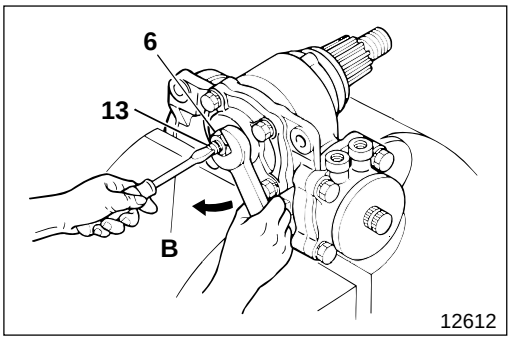


● **Adjustment after assembly**

Adjustment of backlash

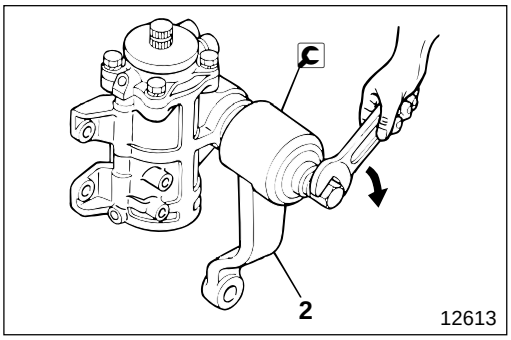
- (Carry out this work with the gears in neutral position.)
  Measure play at the end of pitman arm **2** with dial gauge **A**, and adjust adjusting screw **13** so that the reading meets the standard value.

  Measuring load : ±15 N {3.3 lbf, 1.5 kgf}



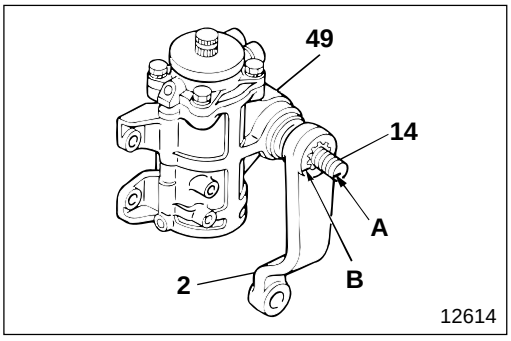
Tightening nut

- After adjusting backlash, apply sealer to thread area of adjusting screw **13**. Hold it in place with screwdriver **B** and tighten nut **6** at specified torque.



2 **Pitman arm**

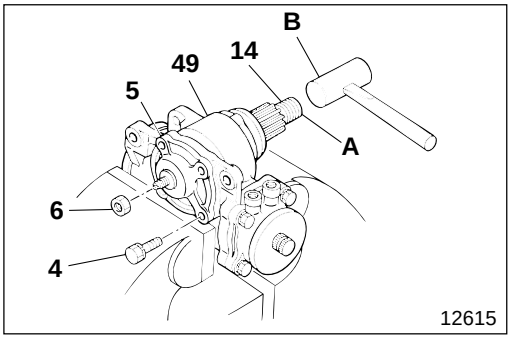
[Removal]



[Installation]
Align slit **A** of the V-groove of sector shaft **14** to the center of body **49**, and align slit **B** of the V-groove of pitman arm **2** on the same line.

NOTE

Have pitman arm 2 make a full stroke of the piston to make sure that the piston moves smoothly.

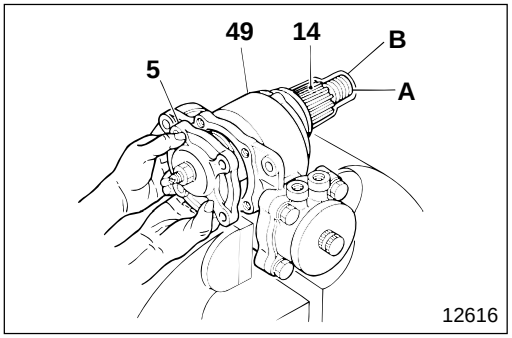


5 **Sector shaft assembly and side cover assembly**

[Removal]

- Make sure that the piston is in the neutral position (slit **A** of the V-groove at one end of sector shaft **14** is aligned with the center of body **49**).
- Tap the end of sector shaft **14** and pull out sector shaft assembly and side cover assembly **5**.

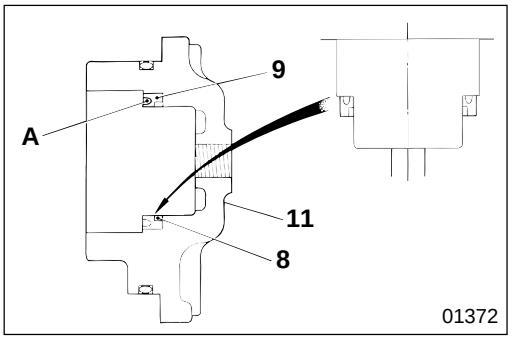
  B : Plastic-headed mallet



[Installation]
Position sector shaft **14** of sector shaft assembly and side cover assembly **5** so that slit **A** of its V-groove is aligned with the center of body **49**, and the piston gear and sector shaft gear engage at their centers.

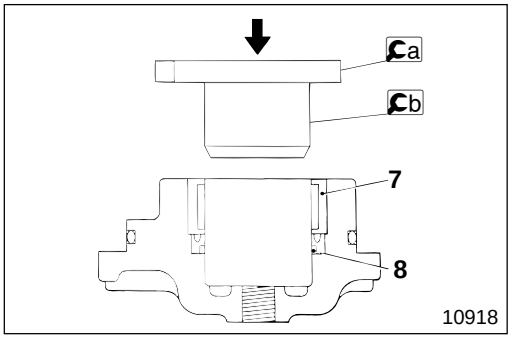
CAUTION

Before installation, apply tape B to the Y-packing to prevent it being damaged by the threads of sector shaft 14.

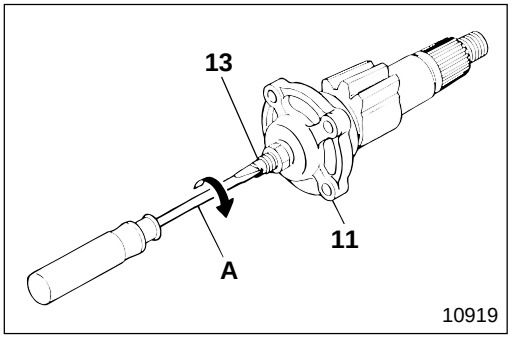


8 **9** **Backup ring, Y-packing**

[Installation]
- Install Y-packing **9** into side cover **11** in the direction as illustrated.
- After installing backup ring **8**, pack groove **A** of Y-packing **9** with grease.

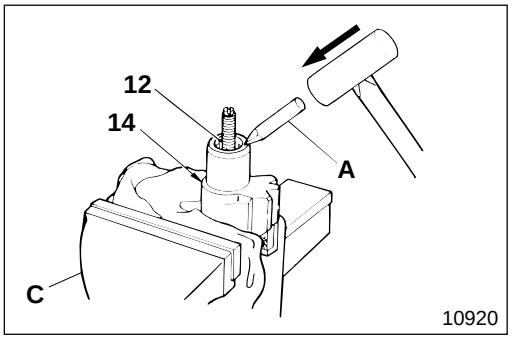


- After installing needle bearing **7** into backup ring **8**, form the bent up part of the backup ring using ca insert tool assembly and cb insert tool.



11 **Removal of side cover**

Screw in adjusting screw **13** and remove side cover **11**.
A : Screwdriver

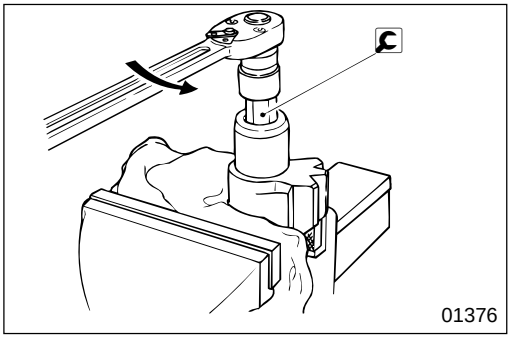


12 **Retainer**

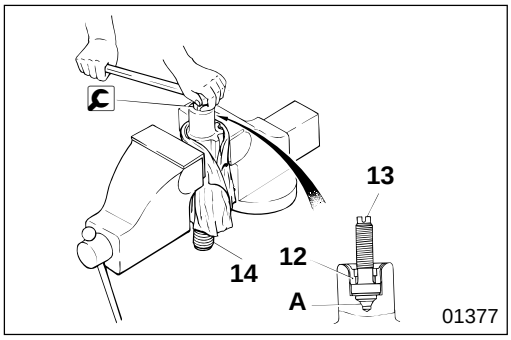
Disassemble sector shaft **14**, as follows, only if it is faulty :
[Removal]
- Pry up (2 points) of retainer **12**.
  A : Chisel

CAUTION

Make sure you use a cloth when you grip sector shaft 14 in vise C to prevent damage.

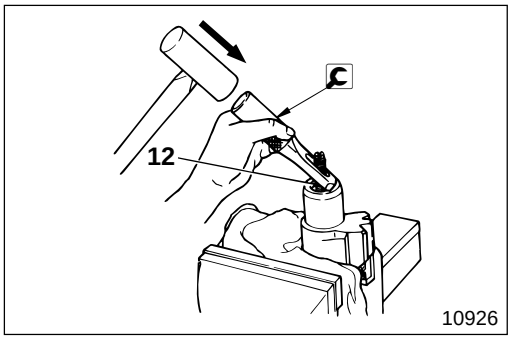


- Remove retainer **12** using [f] bar.

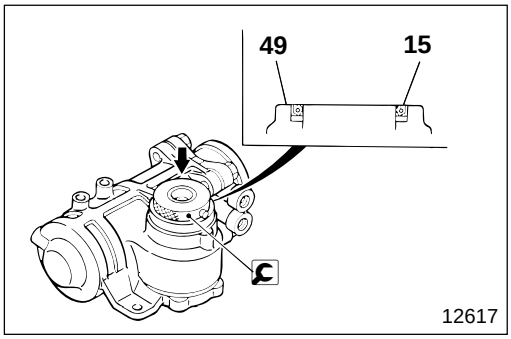


[Installation]

- Pack adjusting screw **13** mounting hole **A** of sector shaft **14** with grease.
- Install adjusting screw **13** into sector shaft **14**.
- Install retainer **12** into sector shaft **14** using [f] bar.
- After installation, slacken off by 180°, retighten at 39 N·m {29 ft.lbs, 4 kgf·m}, then slacken off by 20°.
- Make sure that adjusting screw **13** turns smoothly.

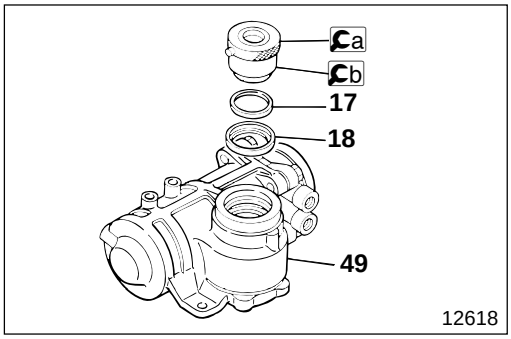


- After installing retainer **12**, caulk the retainer (2 points) using [f] squeeze tool.



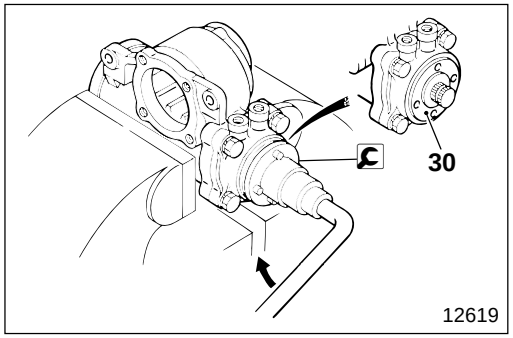
15 **Installation of oil seal**

Install oil seal **15** into body **49** in the direction as illustrated.



17 **18** **Installation of backup ring and Y-packing**

- Install Y-packing **18** and backup ring **17** to body **49**.
- Pack the groove of Y-packing **18** with grease.
- Form the shape of backup ring **17** using [fa] insert tool assembly and [fb] insert tool.



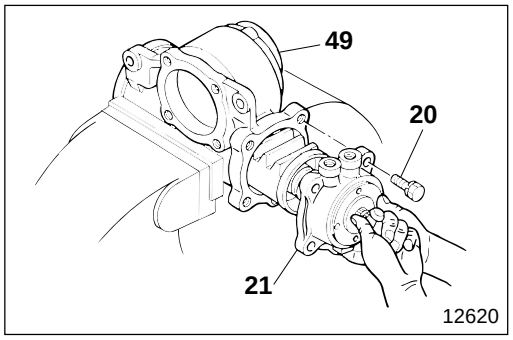
21 **Ball screw assembly**

[Removal]

- Loosen adjusting plug assembly **30** by approximately 180° using wrench assembly.

CAUTION

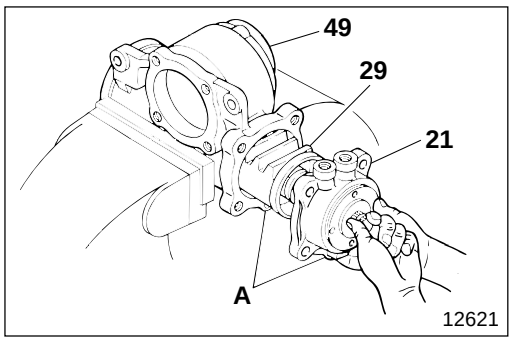
Make sure you only loosen adjusting plug assembly 30, do not undo it completely because the bearing inside the valve housing might spring out.



- Loosen bolt **20** and remove ball screw assembly **21** from body **49**.

CAUTION

- **Make sure that the balls of the ball screw do not spring out.**
- **Be careful not to damage the piston or the interior of body 49.**



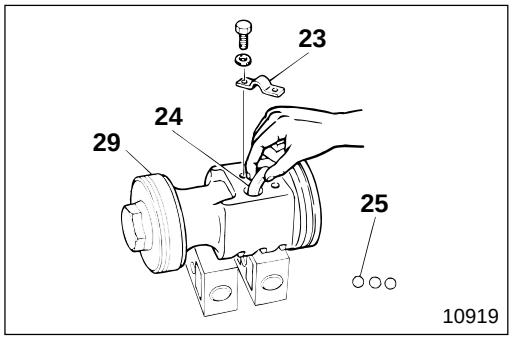
[Installation]

- Install ball screw assembly **21** into body **49**, holding piston **29** so it will not turn.

CAUTION

Be careful not to damage the piston seal ring or the interior of body 49.

- Align oil passage ports **A** of ball screw assembly **21** and body **49**, then tighten.

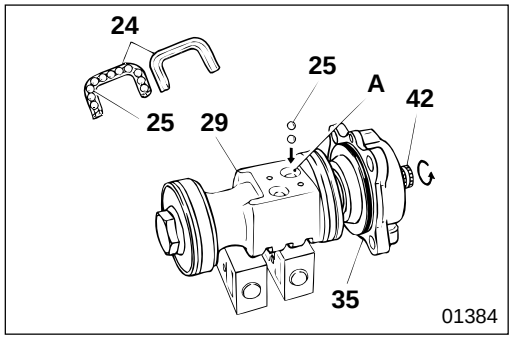


24 **25** **Ball tube and steel ball**

First remove steel balls **25** from piston **29** and place them in the receiving tray, remove ball clip **23**, grip ball tube **24** with your fingers and pull it out gently.

CAUTION

Be careful not to loose any steel balls 25 (×30).

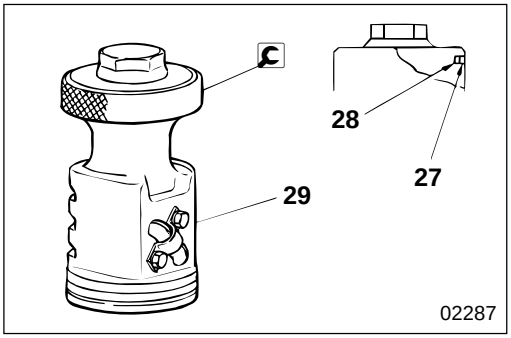


[Installation]

- Pack the interior of ball tube **24** with grease, lay 10 or 11 steel balls **25** in place, then mount the other side of the ball tube.
- Place piston **29** on a level surface, align assembled worm shaft assembly and valve housing assembly **35** and the piston ball race, then drop the steel balls through ball tube hole **A** while turning stub shaft **42**.

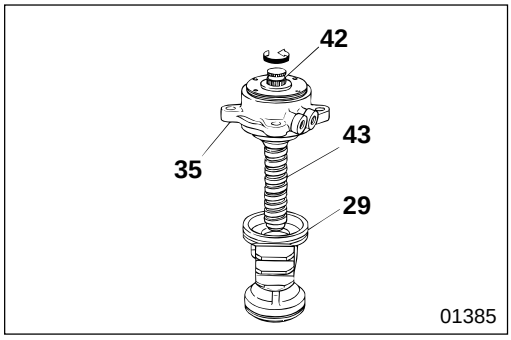
CAUTION

Make sure that you do not pull out worm shaft assembly and valve housing assembly 35 too far, or steel balls 25 will drop out of the ball race.



27 **28** **Installation of O-ring and seal-ring**

Install O-ring **28** and seal ring **27** in the outside grooves of piston **29**, then form the shape of the seal ring with 🔧 inserting tool.

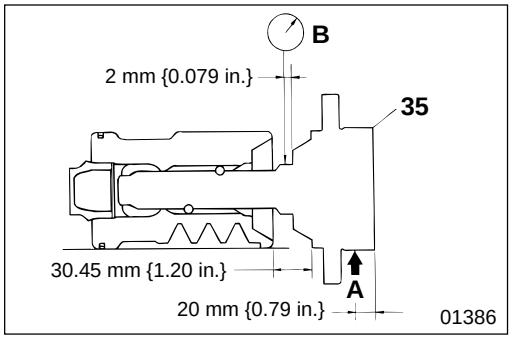


29 **Piston**

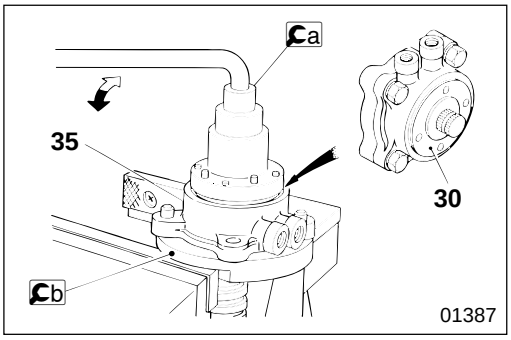
[Removal]
Holding worm shaft assembly and valve housing assembly **35** so that piston **29** is at the bottom, turn stub shaft **42** and remove the piston.

CAUTION ⚠

Be careful not to tilt piston 29 when you do this, otherwise steel balls 25 in the races of the piston and worm shaft 43, will drop into the piston.

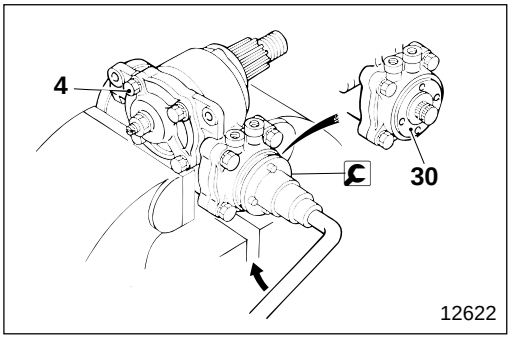


[Inspection]
Measure side play (play in axial direction) **B** of worm shaft assembly and valve housing assembly **35** when 49 N {11 lbf, 5 kgf} is applied to **A** as illustrated.

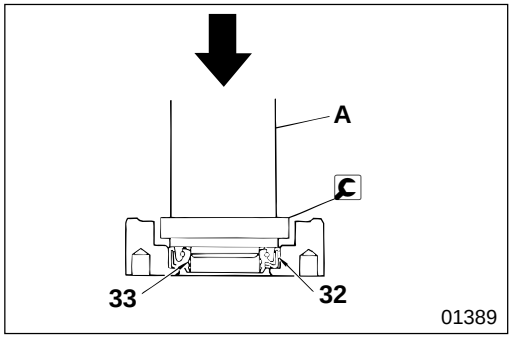


30 **Installation of adjusting plug assembly**

- After tightening adjusting plug assembly **30** of worm shaft assembly and valve housing assembly **35** at specified torque, slacken off by approximately 180°.

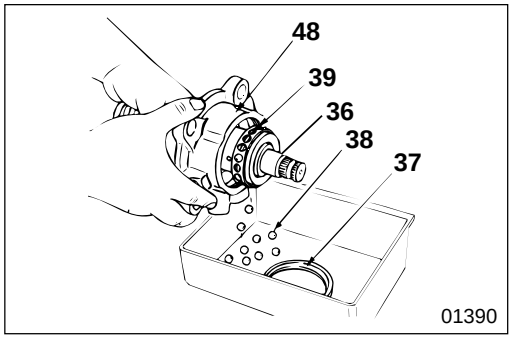


- Tighten bolt **4** at specified torque, then retighten adjusting plug assembly **30** at specified torque using 🔧 wrench assembly.



32 **Installation of oil seal**

Install oil seal **32** into adjusting plug **33** in the direction as illustrated.
A : Hand press



36 **Worm shaft assembly**

[Removal]
Push out worm shaft assembly **36** from valve housing **48** by pushing out the side of the worm shaft assembly where the piston is assembled.

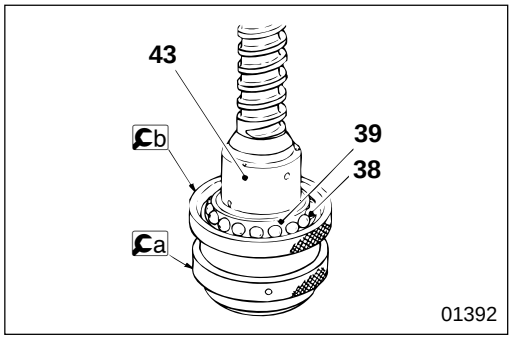
NOTE

Have a tray or box ready to catch side race 37, steel balls 38, and bearing cage 39 as these items separate on removal.

[Installation]

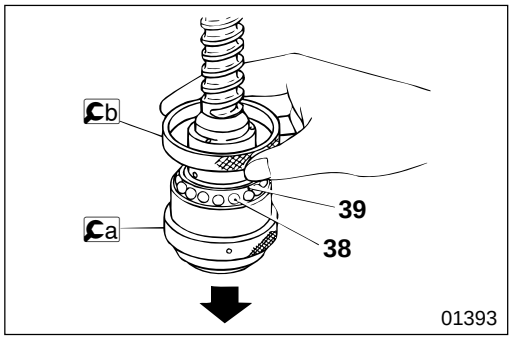
CAUTION

Be careful that worm shaft assembly 36 ball race does not damage seal ring 44.

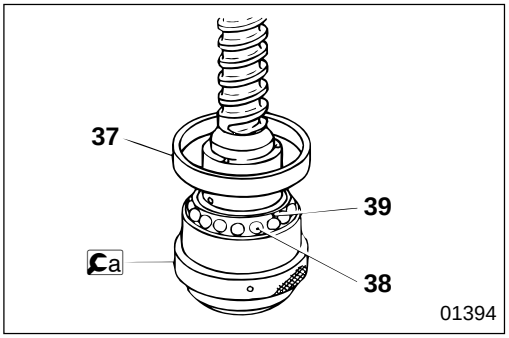


37 **to** **39** **Installation of side race, steel ball, and bearing cage**

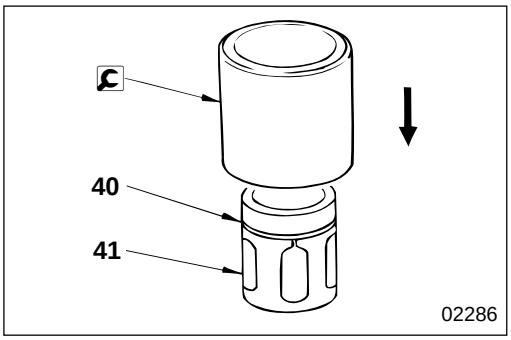
- Install b guide assembly on a tool assembly, and insert worm shaft **43** in the direction as illustrated.
- Assemble bearing cage **39** and steel balls **38** on worm shaft **43**.



- Hold down b with your hand and slide a downward, so that you can position steel balls **38** as specified.

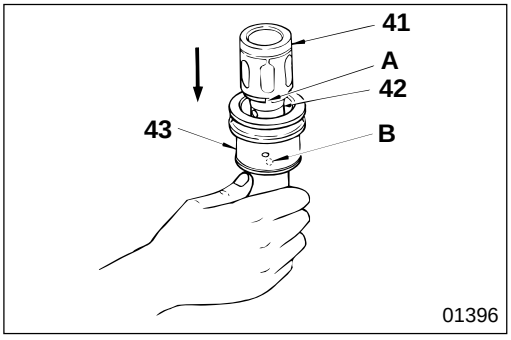


- Install side race **37** on top of steel balls **38** and bearing cage **39**.



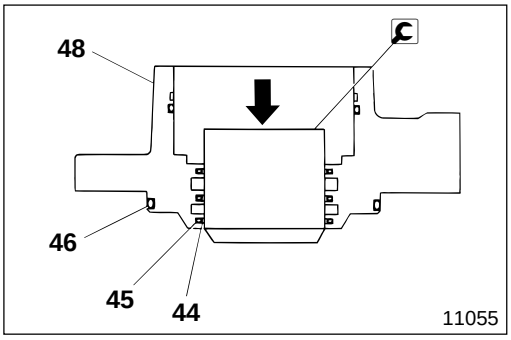
40 **Installation of seal ring**

- Install seal ring **40** onto rotor **41**.
- Form seal ring **40** using insert tool.



41 **Installation of rotor**

Install rotor **41** between stub shaft **42** and worm shaft **43** so that indent **A** of the rotor fits positioning pin **B** of the worm shaft.



44 **to** **46** **Installation of seal ring and O-ring**

- Install seal ring **44** and O-ring **45**, **46** into valve housing **48**.
- Form seal ring **44** using insert tool.

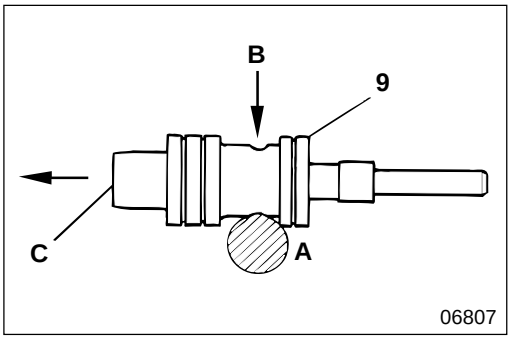
◆ Service procedure



9 **Inspection of air-tightness of relief valve section in flow control valve assembly**

- Cover port **A** of flow control valve assembly **9** with a finger.
- Apply air pressure of 390 to 490 kPa {57 to 71 psi, 4 to 5 kgf/cm²} to port **B**.
- Check port **C** for air leakage.
- If abnormalities are found, replace body & shaft assembly **22**.

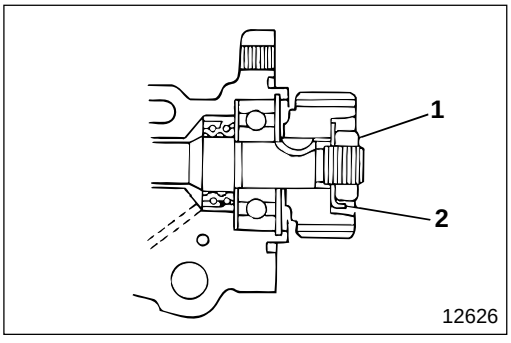
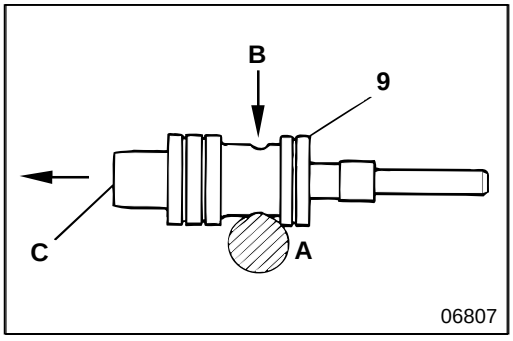
◆ Service procedure



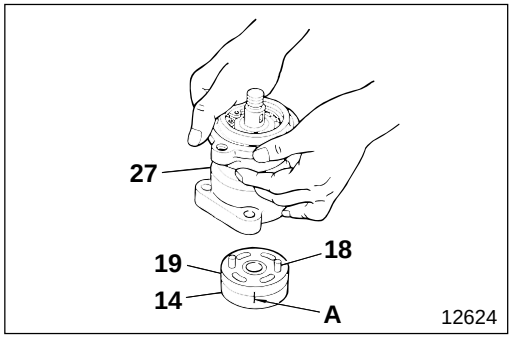
2 Installation of lock washer

After installing nut **1**, bend up one lug on the circumference of lock washer **2**.



9 Inspection of air-tightness of relief valve section in flow control valve assembly

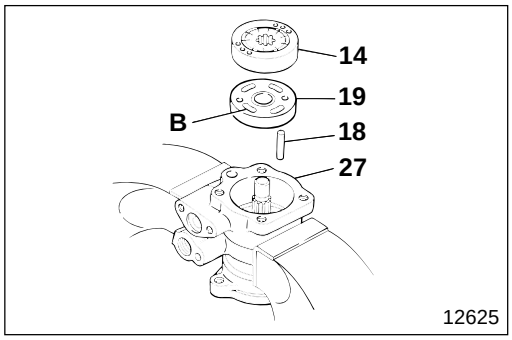
- Cover port **A** of flow control valve assembly **9** with a finger.
- Apply air pressure of 390 to 490 kPa {57 to 71 psi, 4 to 5 kgf/cm^2} to port **B**.
- Check port **C** for air leakage.
- If abnormalities are found, replace front body assembly **27**.



14 **Removal and installation of cartridge assembly**

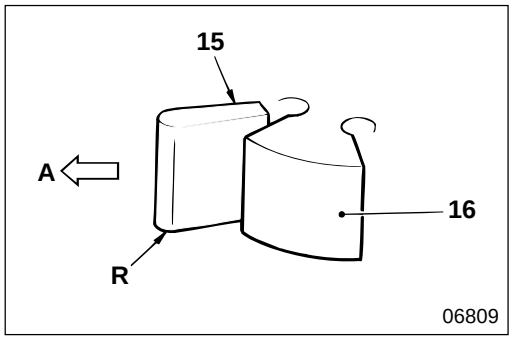
[Removal]

- Remove cartridge assembly **14**, pressure plate **19** and straight pin **18** together from front body **27**.
- Put alignment marks **A** around the outer circumferences of cartridge assembly **14** and pressure plate **19**.



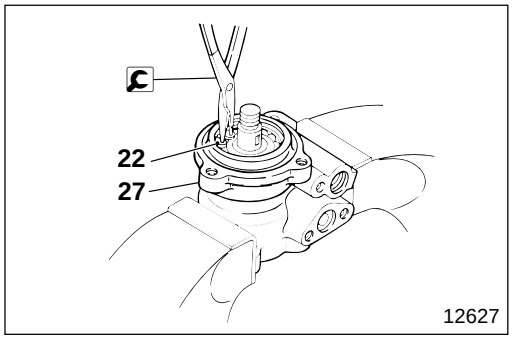
[Installation]

- Install straight pin **18** into front body **27**.
- Install pressure plate **19** onto front body **27**, so that groove **B** of the pressure plate faces the direction as illustrated.
- Align cartridge assembly **14** with straight pin **18**, then install the cartridge assembly.



15 **Installation of vane**

With point **R** of vane **15** facing outside **A**, install it into rotor **16** and make sure that the vane moves smoothly. If it is faulty, replace the cartridge assembly.



22 **Removal of retaining ring**

[Removal]

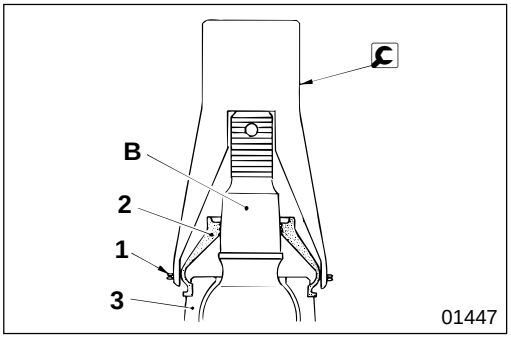
A : Long nose pliers

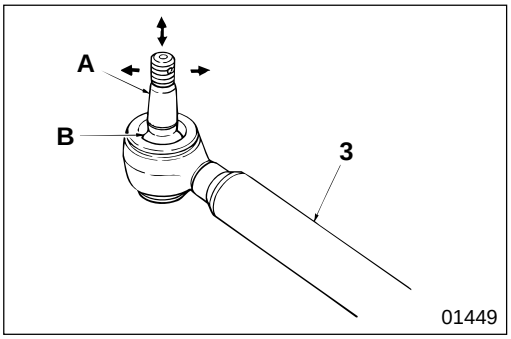
CAUTION

- **Be careful not to damage clip 1 or dust cover 2 when you remove the clip.**
- **If clip 1 is deformed, do not reuse it.**



[Installation]
- Position the assembly so ball stud **B** is vertical.
- Place clip guide on drag link **3**.
- Install clip **1** into the groove of dust cover **2**.

CAUTION
- **Be careful that clip guide end does not dig into dust cover 2.**
- **Be especially careful that clip 1 end does not damage dust cover 2.**



3 Inspection of drag link

Move ball stud area **A** of drag link **3** vertically and horizontally to make sure that there is no play. Also, check that ball section **B** moves evenly. If any fault is found, replace the tie rod assembly.

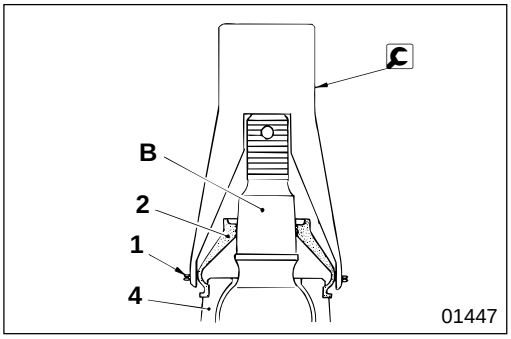
CAUTION

- **Be careful not to damage clip 1 or dust cover 2 when you remove the clip.**
- **If clip 1 is deformed, do not reuse it.**

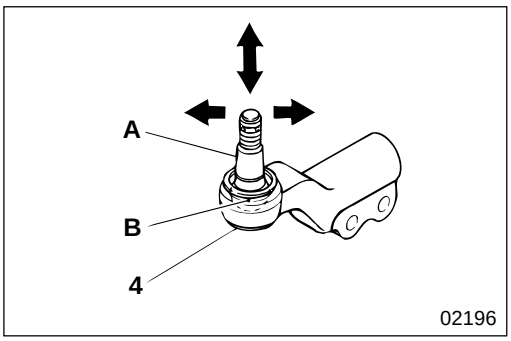


[Installation]

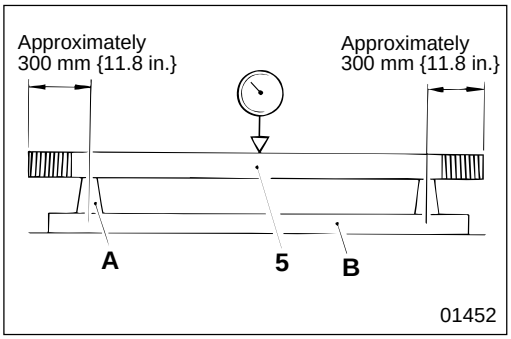
- Position so ball stud **B** is vertical.
- Place clip guide on tie rod end assembly **4**.
- Install clip **1** into the groove of dust cover **2**.

CAUTION

- **Be careful that clip guide end does not dig into dust cover 2.**
- **Be especially careful that clip 1 end does not damage dust cover 2.**



Move ball stud area **A** of tie rod end assembly **4** vertically and horizontally to make sure that there is no play. Also, check that ball section **B** moves evenly. If any fault is found, replace the tie rod end assembly.



5 Bend of tie rod

Measure the bend of tie rod **5** at the center point. If the measured value exceeds the limit, correct or replace the tie rod.

NOTE

To measure the deflection of tie rod 5, turn it one full rotation and read the dial gauge indicator. The deflection is one half of the indicated value.

◆ Service procedure

● Cleaning of frame

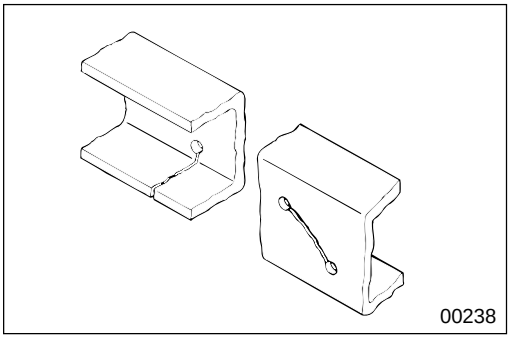
Carefully remove mud, grease, rust, etc. that is stuck to the outer and inner surfaces of the frame.

● Inspection for frame deformation

If any fault such as deformation is found, repair the frame.

● Inspection for cracks in frame

- Remove paint from any areas that are seemingly faulty and carefully inspect.
- If visual inspection is difficult, inspect using color contrast penetrant examination or other methods.
  If a crack is found, repair as follows.

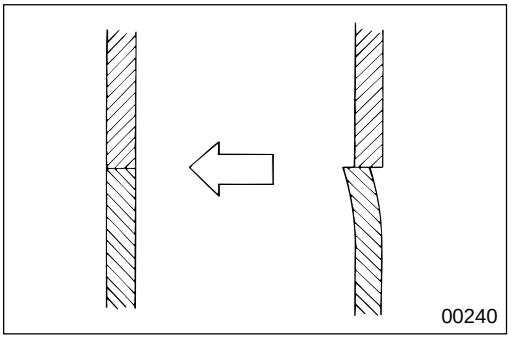


● Repair of crack in frame

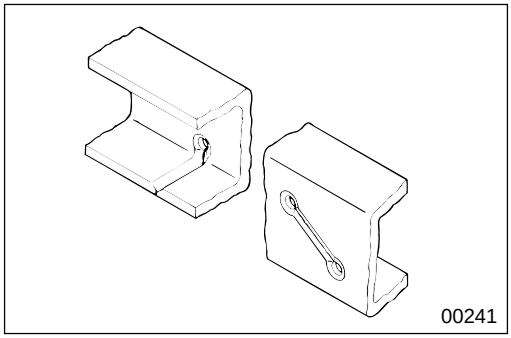
- With the vehicle unloaded, level the frame.
- Drill a hole, about twice the thickness of the frame, 10 mm {0.39 in.} from the end of the crack.

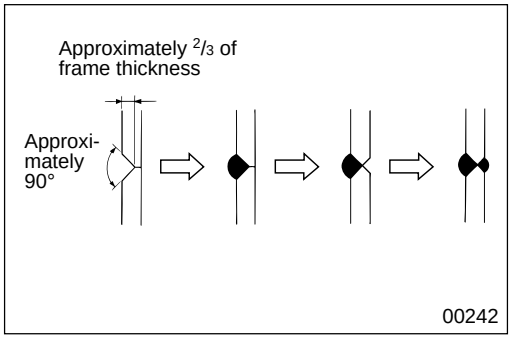
NOTE

If a crack is found inside the frame, drill holes at both ends of the crack.



- If the edges of the crack are not flush, make them flush with each other.





- Using a grinder, etc., grind a 90° V-section channel, two-thirds of the frame thickness, then weld.

WARNING

You must cover any inflammable materials, such as pipelines, wiring harnesses, rubber parts, and the fuel tank, that are near the welding site.

CAUTION

- **Do not use gas welding because the high temperature produced alters the material properties and weakens the welded area. Be sure, therefore, to use electric welding.**
- **Be sure to remove the negative terminal of the battery, then ground the welder near the area to be welded to prevent reversed flow of current from the welder which might burn out electrical components.**
- **Be sure to protect mountings such as main sills that can be damaged by heat, by using heat insulators, etc.**

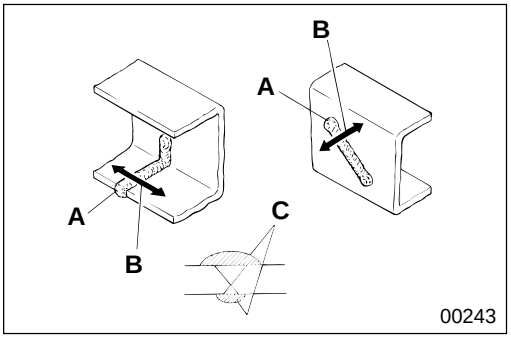
NOTE

- **Use low-hydrogen type coated CO_2 and arc welding electrodes for welding to prevent harmful defects such as undercutting, blow holes, etc.**
- **Preheat the area to be welded to approximately 50 to 350°C {122 to 662°F} before welding when the workshop temperature is below 0°C {32°F}.**

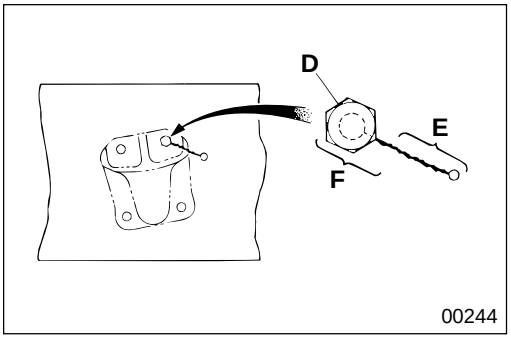
- Next, grind a V-section channel, as described above, on the opposite side of the weld and weld. At the same time, fill the holes at both ends of the crack by welding.

NOTE

In cold districts, heat the welded area to approximately 200°C {392°F} after welding.

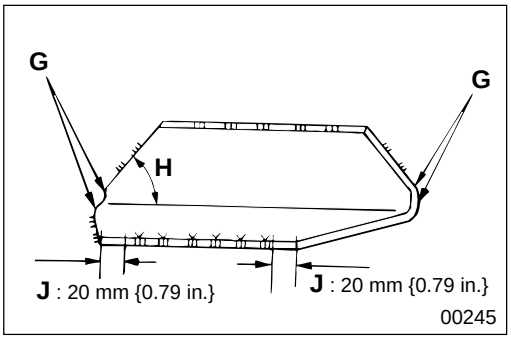


- After welding, grind bead **A** at right angles **B** to remove shaded area **C** as illustrated and grind the area flat.
- Finish the surface so that the frame thickness is identical to the original thickness.



[Repairing cracks caused by rivets or bolt holes]

- To make the edges of the holes flush at the cracked area, temporarily tighten bolt **D** in the hole.
- Weld cracked point **E** at least 20 mm {0.79 in.} from the center of the bolt.
  For welding method refer to the above-mentioned procedures for repairing cracks. P41-3
- After removing the bolt and making the edges flush, weld remaining area **F** and fill the hole.
- After drilling a hole in the filled area, install a rivet or bolt.

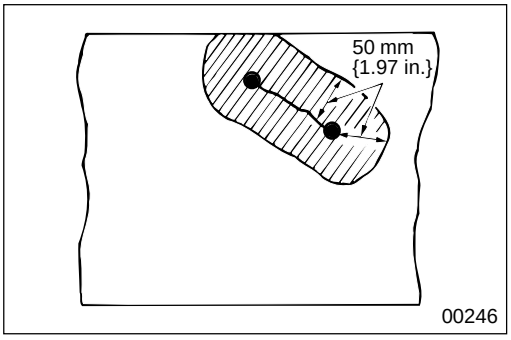


[Repairing using reinforcement plate]

- To prevent concentrated stress being produced at ends **G** of the reinforcement plate, weld the plate with angle **H** at both ends opened 30° or less.
  Do not weld area **J**.
- The reinforcement plate must have enough strength for the cracked area.

NOTE

- **Thickness of reinforcement plate : same as frame thickness**
- **Reinforcement plate material : HTP540 (high tensile strength steel) or equivalent strength.**

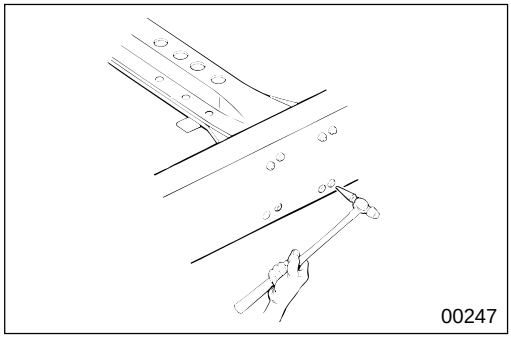


- After welding, heat the shaded area to 600 to 700°C {1112 to 1292°F}.

CAUTION

Be sure to protect mountings such as main sills that can be damaged by heat, by using heat insulators, etc.

INSPECTION AND REPAIR OF FRAMES

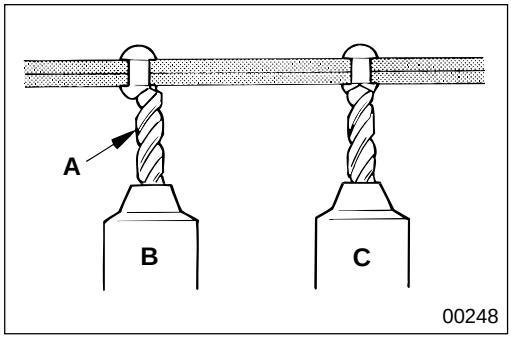


● **Inspection for loose rivets**

- Gently tap the rivet head using an inspection hammer and judge the condition by checking the vibration using the tip of your finger, or by listening to the sound.
- Rust between rivet and frame indicates that the rivet is loose.

CAUTION

Be sure to replace loose rivets because they can break or cause cracking of the frame in the area around the rivet hole, causing accidents.

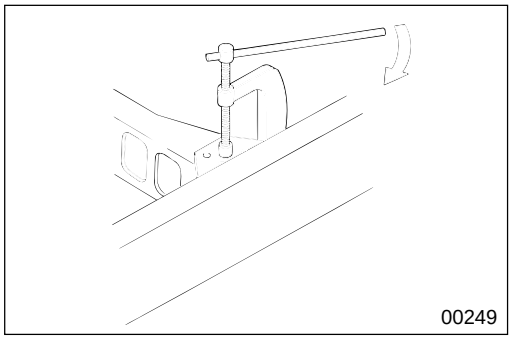


● **Repair of rivet**

- When removing rivets, use a center punch to make an indent in the center of the rivet head; then, drill out using drill **A** or grind.
  B : Incorrect
  C : Correct

CAUTION

Make sure that you do not damage the rivet hole.



- When rivetting, first clamp both plates tightly near the rivet hole using a clamp to eliminate gaps between plates.

- Using a rivetting machine, insert the rivet (cold rivet).
- If rivetting is impossible, ream the rivet hole, drive in a reamer bolt, fully tightening the nut, then weld it in place.
  A flange bolt and flange nut should be used for the reamer bolt and nut.

● **Inspection for loose bolts and nuts**

- Inspect the mounting bolts of the cross member and the helper stopper for looseness. Loosened bolts should be tightened at specified torque. P41-2, Gr 34

NOTE

Tighten the nut side when working on the helper stopper mounting bolts.

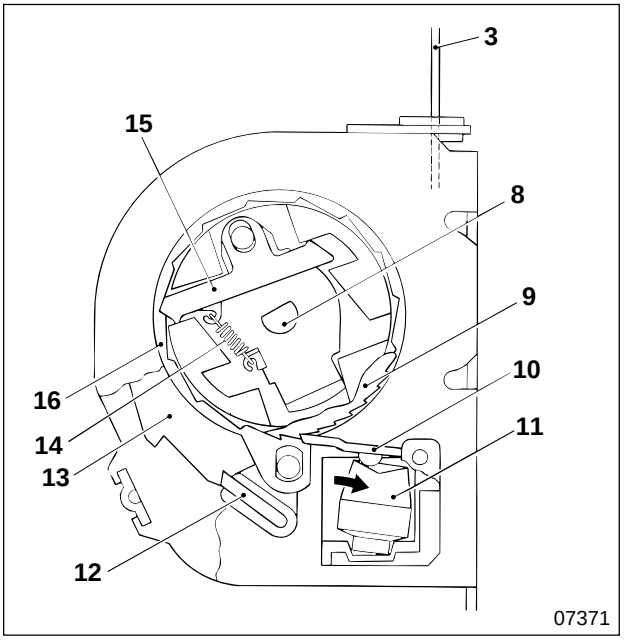
CAUTION⚠

Do not disassemble emergency locking retractor assembly 7, or malfunctions might occur.



Webbing detecting lock

- When the vehicle is subjected to a sudden impact, such as a crash, webbing **3** retracts according to the movement of passengers, and spindle **8** rotates.
- As the rotation of spindle **8** is higher than the specified value, the repercussive force of sensor spring **14** can no longer retain lock arm **15**. Then, the arm is pulled out from the specified position and is locked by clutch **16**.
- If spindle **8** further rotates, clutch **16** lifts pawl **12** to lock with ratchet gear **13**, making spindle rotation impossible.

Body detecting lock

- When the body is tilted excessively, mechanism weight **11** is tilted, engaging mechanism lever **10** with locking gear **9**, locking it.
- If spindle **8** further rotates, clutch **16** operates as described above, and the spindle cannot rotate.

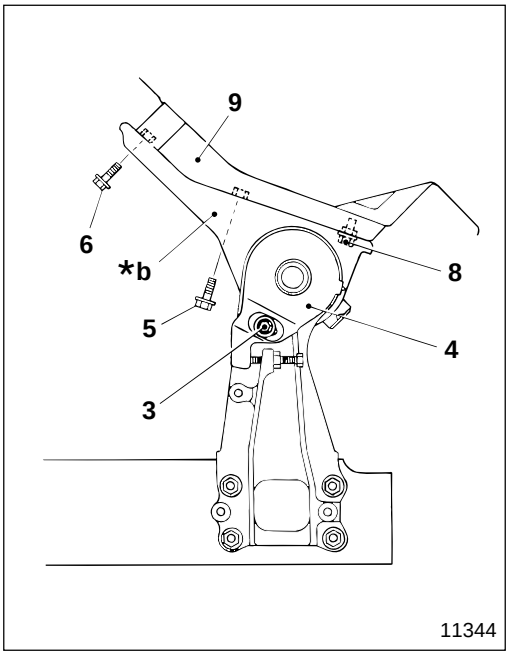
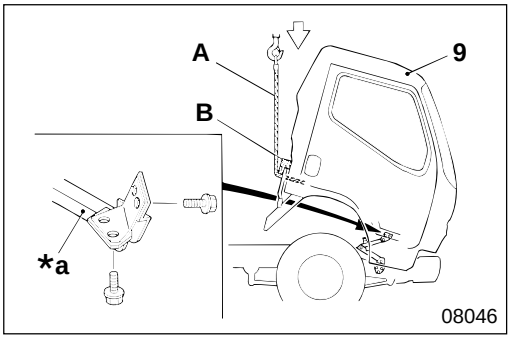
◆ Service procedure



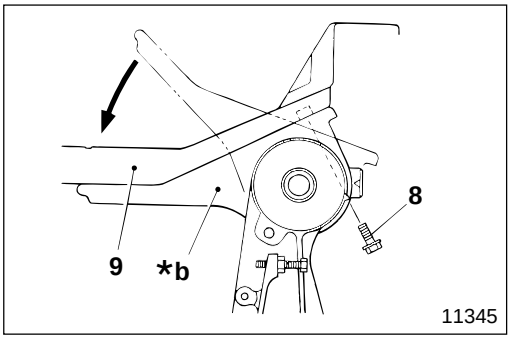
9 **Cab assembly**

[Removal]

- Tilt cab assembly **9** and lock cab stay ***a** securely.
- Remove bolt **3**, and remove anchor lever **4**.
- Of the three bolts that retain front floor cross member ***b**, remove bolts **5**, **6** at rear side, leaving bolt **8** at front side.

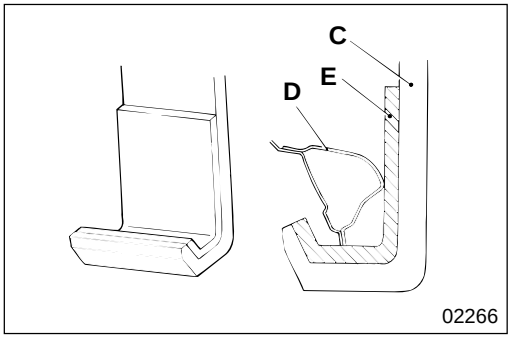


- To separate cab stay ***a** from cab assembly **9**, support the cab securely using crane **A** that is capable of lifting the cab.
  B : Use a wood block for protecting the rear of the cab
- Using crane **A**, lower cab assembly **9** until cab stay ***a** can be removed, then remove it.



- Fully lower cab assembly **9** to remove remaining bolt **8** that retains front floor cross member ***b**.

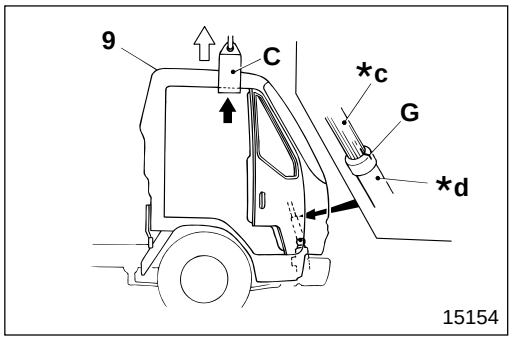
REMOVAL AND INSTALLATION OF CAB



- Set up hoist attachment **C** for the cab as illustrated.

CAUTION

- **Make sure when you set up hoist attachment C that it is capable of lifting cab assembly 9 which weighs approximately 390 kg {860 lb}.**
- **Make sure you install rubber E on hoist attachment C to prevent cab roof D being deformed when the cab is lifted.**



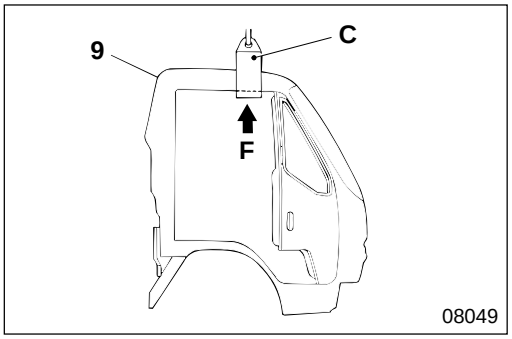
- Mount hoist attachment **C** at center-of-gravity point **F** of cab assembly **9**. Verify the position at which the cab can be lifted horizontally when the cab is lifted slightly.
- Slowly lift cab assembly **9** straight up, and finish lifting when steering yoke ***c** is pulled out from steering shaft ***d**. Make alignment mark **G** before the steering yoke is pulled out from the steering shaft.

WARNING

Never get under cab assembly 9 when it is being lifted.

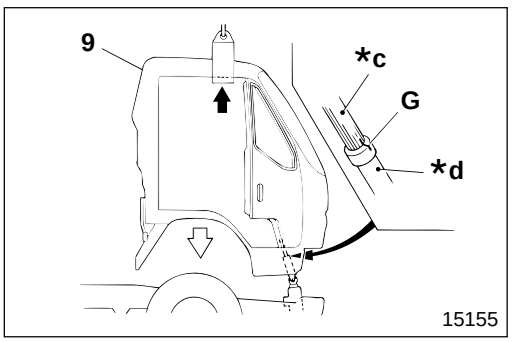
CAUTION

Make sure, when lifting cab assembly 9, that the wiring harness, cable, hoses, etc. are completely disconnected when the cab is lifted slightly.

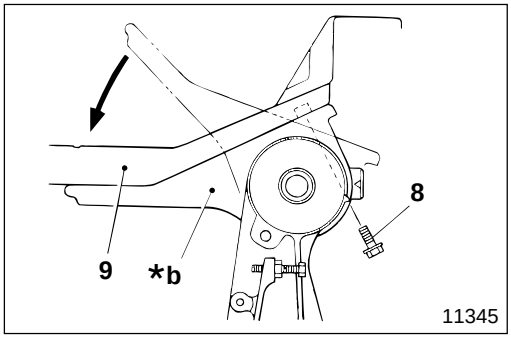


[Installation]

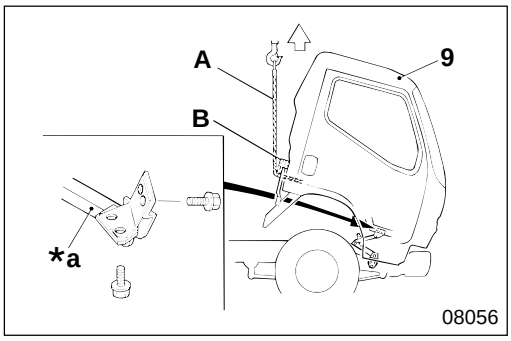
- Mount hoist attachment **C** at center-of-gravity point **F** of cab assembly **9**.



- Slowly lower cab assembly **9** horizontally to insert steering yoke ***c** into steering shaft ***d**, aligning alignment mark **G**.



- Slowly lower cab assembly **9** further, and remove hoist attachment **C** after it comes down fully.
- Tighten front bolt **8**, one of the three bolts used for installing front floor cross member ***b**.

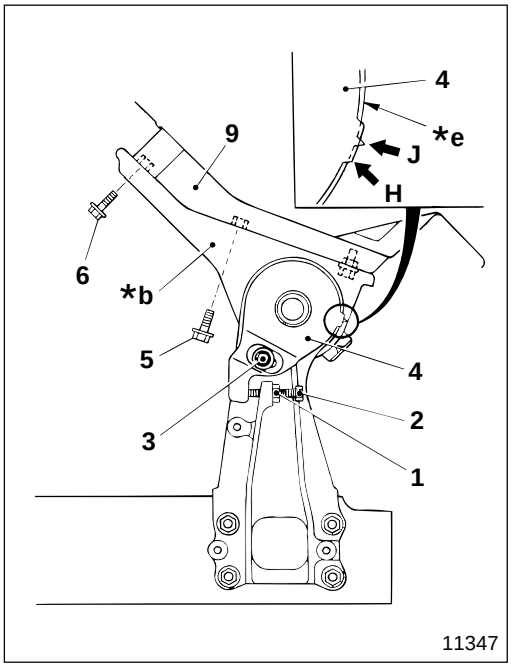


- Securely support cab on crane **A** to tilt cab assembly **9**.
  B : Use a wood block for protecting the rear of the cab
- Using crane **A** tilt cab assembly **9**, and install cab stay ***a**.

WARNING

You must pay close attention to the tilt angle when tilting cab assembly 9 using crane A. It is very dangerous to tilt the cab excessively because it will topple over.

- After installing cab stay ***a**, tilt cab assembly **9** slowly until it is completely tilted, securely lock cab stay, then detach the cab from crane **A**.



- Tilt cab assembly **9**, and securely lock cab stay ***a**.
- Tighten bolts **5**, **6** to install front floor cross member ***b**.
- Position and install pointer **J** of front cab mounting bracket ***e** in convex area **H** of anchor lever **4** and fix it with bolt **3**.
- Position bolt **2** on anchor lever **4** and lock it with nut **1**.
- After mounting cab assembly **9**, check and adjust the operating force required for the lock handle. P42-19

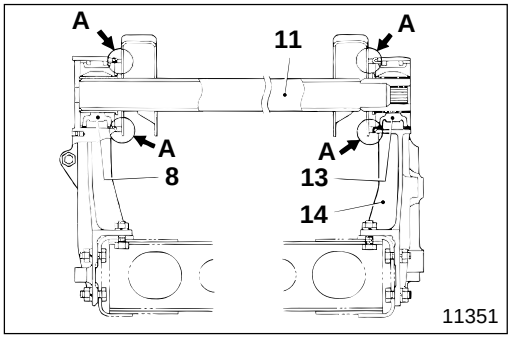
10 **Installation of torsion bar**

Install torsion bar **10** to front floor cross member assembly **11** in the direction as illustrated.

CAUTION⚠

Be sure not to mistake the left side for the right side, when installing torsion bar 10, because the torsion bar will be damaged if its torsion direction is reversed.



11 **Installation of front floor cross member assembly**

Install front floor cross member assembly **11**, adjusting front cab mounting bracket LH **14** so there is no gap between the front floor cross member assembly and front rubber assembly RH **8** and LH **13** at points **A**.

- Remove screws **1** (two points) from front grilles **2**.
- Lift up the ends of clips **C** (two points), located in the center of front grilles **2**, using a screwdriver, and unlock them from the clips.
- Pull out front grilles **2** horizontally, in the vehicle forward running direction, to remove them.

CAUTION

- **Be careful not to apply too much force to front grilles 2, because this would damage them. Be especially careful to avoid applying force to clips D at both sides, support the clips using your hands. If it is hard to remove the front grilles, remove them using nylon jig E as illustrated.**

◆ Service procedure

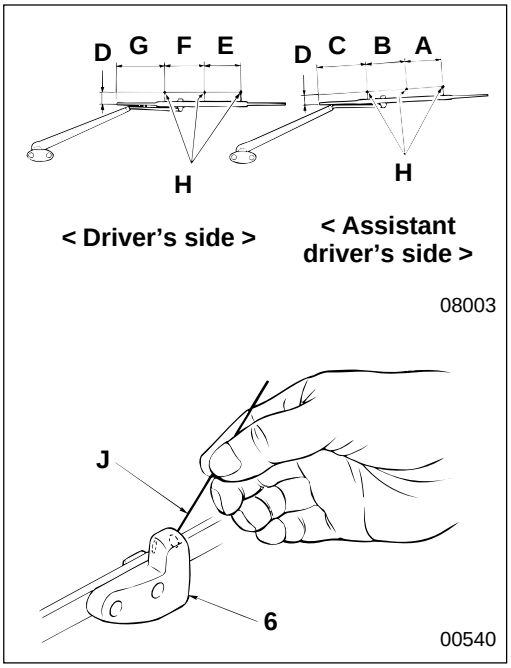
2 **Installation of wiper arm and blade assembly**

Install wiper arm and blade assembly **2** so that dimensions from the edges of the weatherstrip are as illustrated.



6 **Inspection of washer nozzle assembly**

Make sure that washer fluid spreading target positions **H** are within dimensions **A** to **G**. (Illustration shows the view from inside cab.)

Unit : mm {in.}

		H
Assistant driver's side	A	110 {4.33}
	B	90 {3.54}

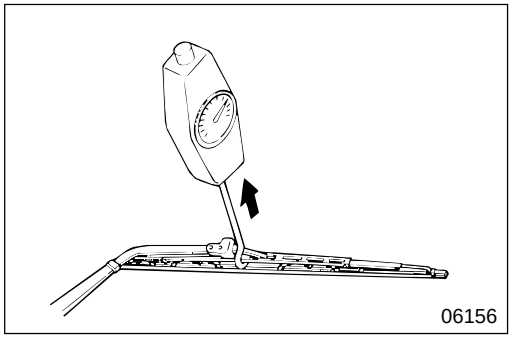
Driver's side	D	15 {0.59}
	E	90 {3.54}
	F	90 {3.54}
	G	160 {6.30}

If washer fluid spreading target positions **H** deviate from these dimensions, adjust the jet hole angle of washer nozzle assembly **6** using wire **J**.

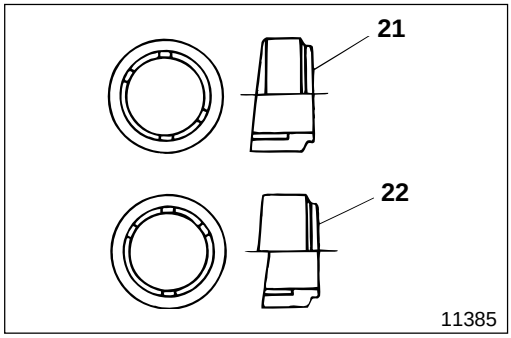
CAUTION⚠

Be careful not to damage the jet hole of washer nozzle assembly 6 with wire J when adjusting the angle.



8 **Inspection of wiper arm**

If the measured value deviates from the standard value, replace wiper arm **8**.



21 **22** **Packing washer**

Because the shape of packing washer **21** for the assistant driver's side and packing washer **22** for the driver's side are different, be careful not to mix them up during assembly.

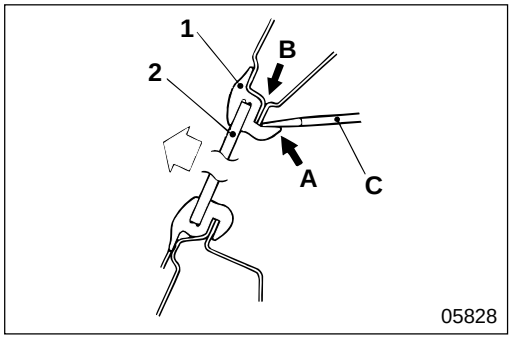
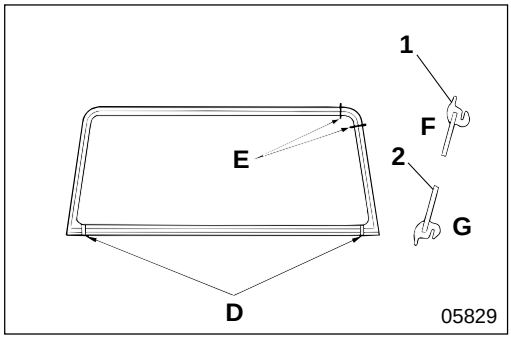
◆ Service procedure



1 **2** **Weatherstrip and windshield**

[Removal]

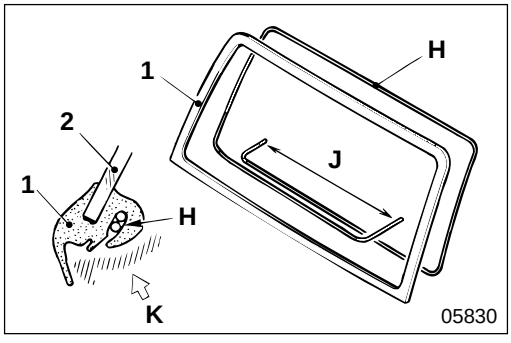
- From the inside of the cab, separate lip **A** of weatherstrip **1** from flange lip **B** of the cab.
  C : Screwdriver
- Push windshield **2** outward to remove it from the cab.



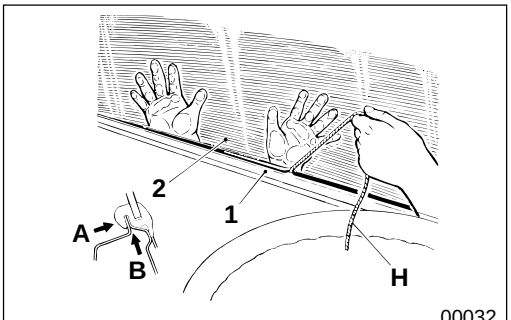
[Installation]

When installing the windshield, pull cord **H** attached to weatherstrip **1** and turn over lip **A**, following the procedure below:

- Position drain hole **D** and joint part **E** of weatherstrip **1** as illustrated and install them on windshield **2**.
  F : Outside
  G : Inside

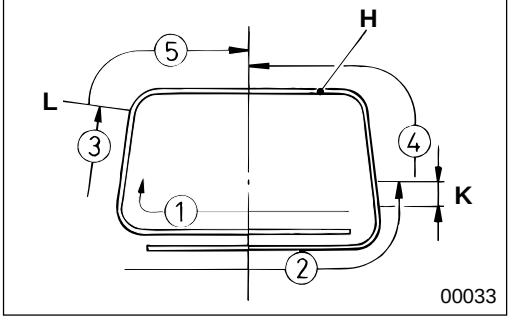


- Lay cord **H** in the cab mounting groove of weatherstrip **1** as illustrated, and overlap the cord at the lower side of the glass by the specified length, see **J**.
- Apply soapy water **K** to weatherstrip **1**.
- Align windshield **2** with the cab.



00032

- Push windshield **2** inward from the outside of the cab firmly.
- Inside the cab, pull one end of cord **H** to install lip **A** of weatherstrip **1** into flange lip **B** of the cab.

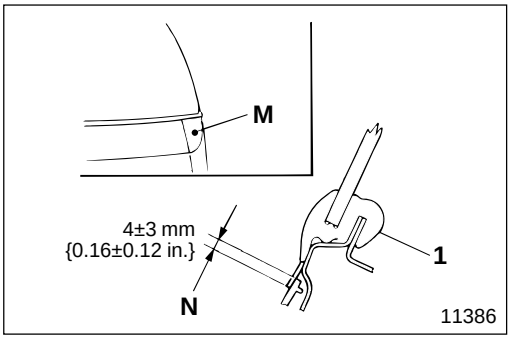


00033

- Pull cord **H** in the numbered order as illustrated and at the same time have someone push windshield **2** into weatherstrip **1**, tapping the windshield with a rubber-headed mallet.
  K : approximately 100 mm {3.94 in.} from the starting point of straight line
  L : up to the end of straight line

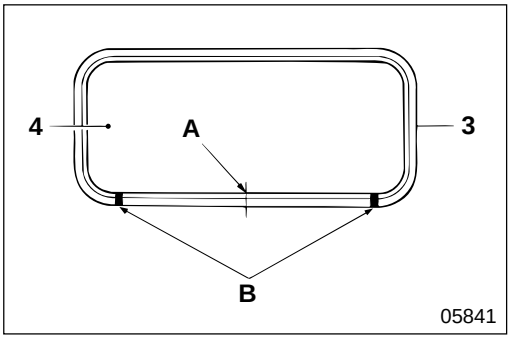
CAUTION⚠

Make sure that windshield 2 is installed correctly into the cab before hitting the windshield with the rubber-headed mallet, otherwise the windshield might be broken.



11386

- Provide an overlapped margin **N** on weatherstrip **1** and side garnish **M** to prevent water flowing backwards from the water drain hole.



05841

3 **4** **Weatherstrip, rear window glass**

- Install so that joint **A** of weatherstrip **3** is at the center of rear window **4**.
  B : Water drain hole
- Except for the point mentioned above, follow the same service procedure as for installation of windshield. 🕮 P42-56

HOW TO READ THIS GROUP

HOW TO READ CIRCUITS (GROUP 54)

1 Index number: (110)

Each circuit has its own Index number respectively and has three digits ((110)).
How to read index number

- By proper using of the index number, it is possible to locate right place immediately since the circuit drawing of this manual book are classified as function by function. (including “POWER CIRCUIT” (110) and “GROUND” (130) .)
- How to check the location of circuit drawing in each part
  The circuit drawing which can not be diagramed in one page due to its complicated structure (such as meter cluster and electronic control unit etc.), has its remarked index number to be connected to other circuit drawing. ((401) , (910) , etc.)

2 Key number: A01~

Key number is the number to indicate the installation position of the parts, and is shown by A01 ~ Z.
The details of the installation position are described in GROUP 10.

3 Code number: **001** ~

Code number is the number to indicate the one portion of the parts to be checked and has three digits (**001**).
The details of the parts to be checked are described in GROUP 11.

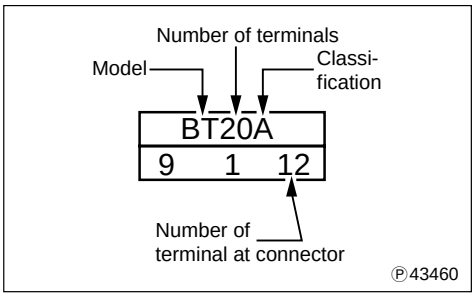
4 Part name

5 Connector type

Connectors are shown by □ without mentioning Male or Female and in the box it is described model of connector, number of terminals and its classification, etc.
Table of connectors is described in GROUP 14.

6 Number of terminal at connector

Terminal numbers of connector are shown by figures in the box.



7 Installation area of harness on the vehicle

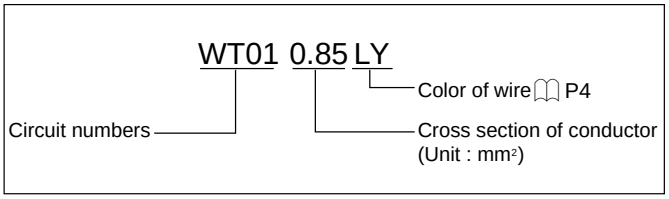
The location and boundary of the harnesses in the vehicle are shown in each circuit drawing and it may help to check mounting position of connectors.

8 Circuits for other specification for other model or type

9 Examples of terminal connector numbering

As it is shown, for female connectors, with placing the lock upward then starting to put numbers from the upper left. And when it is male connector, put numbers from the upper right, also with placing the lock upward.

10 Circuit number, color of wire, and cross section of conductor are shown in circuit drawings.



Except for 0.5mm², Wire thickness is described in the circuit drawing. The reason why only wire thickness, 0.5 mm² is not described in the drawings is 0.5mm² is so common and so that the circuit drawing can be seen more easily.
(Examples) 0.5mm²: Y
0.85mm²: 0.85 — LY
3mm²: 3 — B

11 Grounding point

The actual locations of grounding points on the vehicle are shown. Refer to (130) for detailed information.

12 Wire connection

When the wires are connected into one point of the harnesses, the circuit drawing shows “Arrow mark”.

CAUTION !
Be careful that direction of the arrow does not show the direction of the electric current flow.

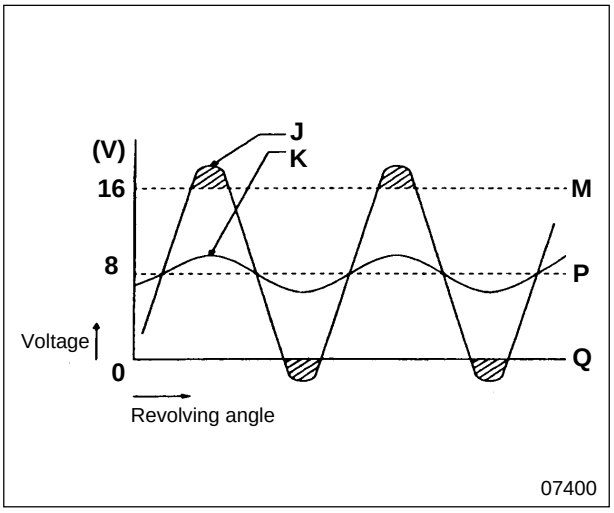
Features of alternator with neutral diodes

- The alternator is the same as the current alternator except neutral diodes **C** and **D** added.
- These neutral diodes **C** and **D** enable this alternator to provide higher DC output during operation at high speeds than the alternator without neutral diodes.

A : Stator coil
B : Alternator terminal B
E : Alternator terminal E
F : IC regulator
L : Alternator terminal L
N : Neutral point
R : Alternator terminal R



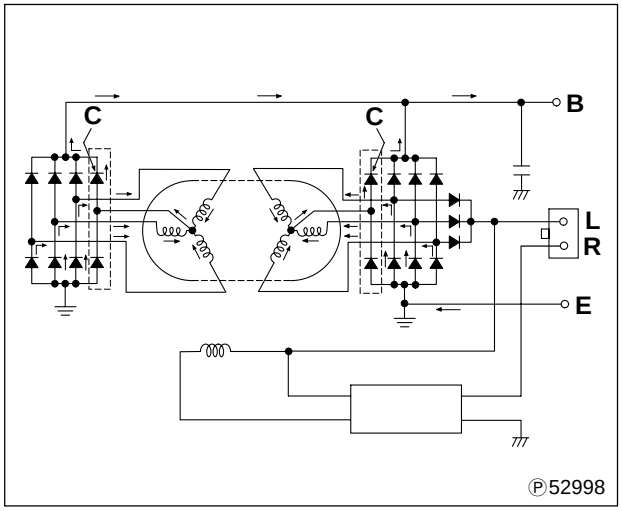
Variations of voltage at neutral point and operation of neutral diodes

- The potential at the neutral point **N** varies up and down with the neutral point DC voltage **P** as a center as shown.
- When alternator is operated at high speeds, the voltage at the neutral point **N** can increase to exceed the output voltage **M** (16 volts) and decrease to become lower than the ground voltage **Q** (0 volt). To adjust these over-voltage and under-voltage (shaded portions of diagram) the current from the excess voltages is taken by neutral diodes **C** and **D** and added to the DC output.

J : Voltage waveform at neutral point during high speed operation
K : Voltage waveform at neutral point during low speed operation
M : Output voltage
P : Average voltage at neutral point (1/2 of output voltage)
Q : Ground potential

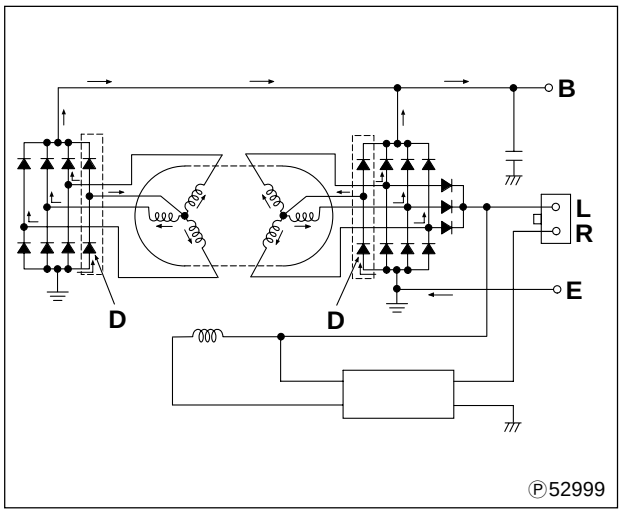
The operation of neutral diodes **C** and **D** for each voltage and potential is as follows.

- When the voltage at neutral point is in the range from 0 to 16 volts, the other 6 diodes are operated. Neutral diodes are not operated.



● **When the voltage at neutral point exceeds 16 volts**

The positive diode **C** adds extra output to the DC output for supply to each electric equipment.



● **When the voltage at neutral point drops below 0 volt**

The negative diode **D** supplies the output from neutral point through other 3 diodes.

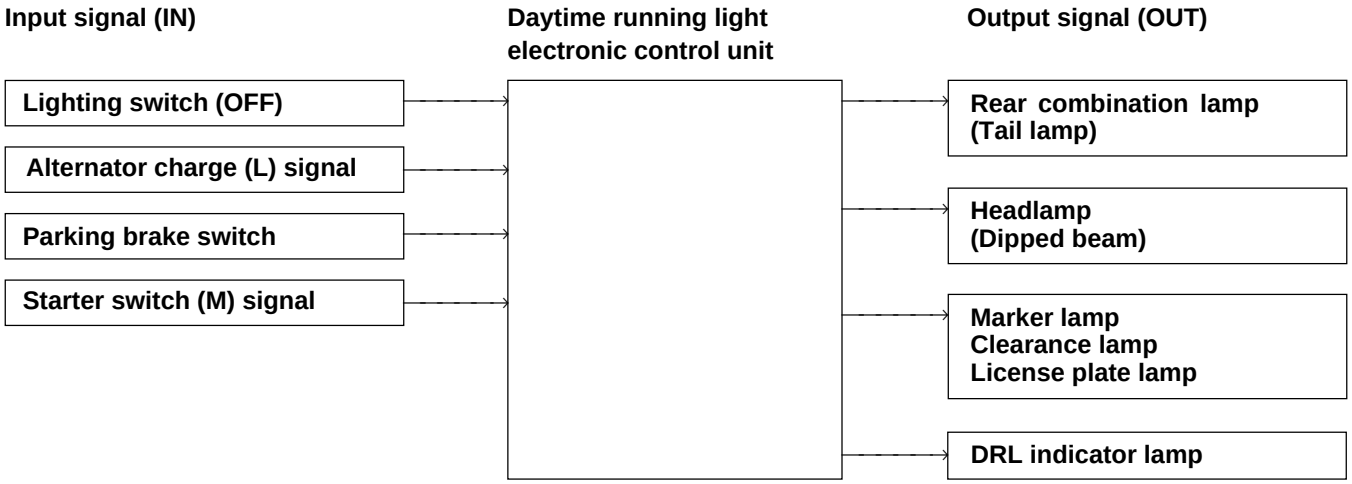
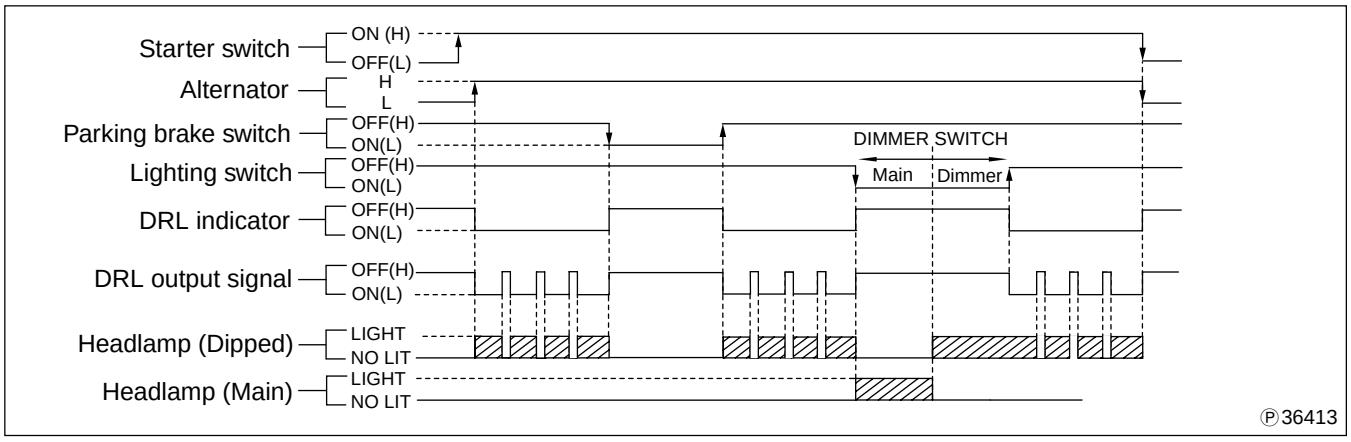
- The headlamp unit consists of sealed beam units **1, 2** separately installed in housing **7**. Sealed beam unit **1** is for Main beam, and sealed beam unit **2** is for Dipped beam.
- The headlamp aiming can be adjusted by changing the installation angle of sealed beam units **1, 2**.
- To adjust the installation angle of sealed beam unit **1**, turn screws **5, 6**. Extension spring **8** sets the angle of the sealed beam unit.
- To adjust the installation angle of sealed beam unit **2**, turn screws **3, 4**. Extension spring **9** sets the angle in the same way as for sealed beam unit **1**.

Daytime running light system



- In a daytime running light system, regardless the position of lighting switch while engine is running, the dipped beam of the headlamp and the tail lamp of the rear combinations, position lamp, license plate lamp will light on.
- Except for that the lighting switch is OFF or when the passing switch is ON, the same lamps as usual switch operation will light.

• Timing chart



Headlamps repeat ON/OFF operations at 120 Hz according to the above timing chart. Because of the cyclic ON/OFF operations, the headlamps are dimmer than when the headlamp switch is ON.

Explanation of timing chart

- After the engine starts, when alternator begins generating electricity with starter switch in the ON position, headlamps light.
- When parking brake switch is ON, the DRL turns off to switch off the headlamps.

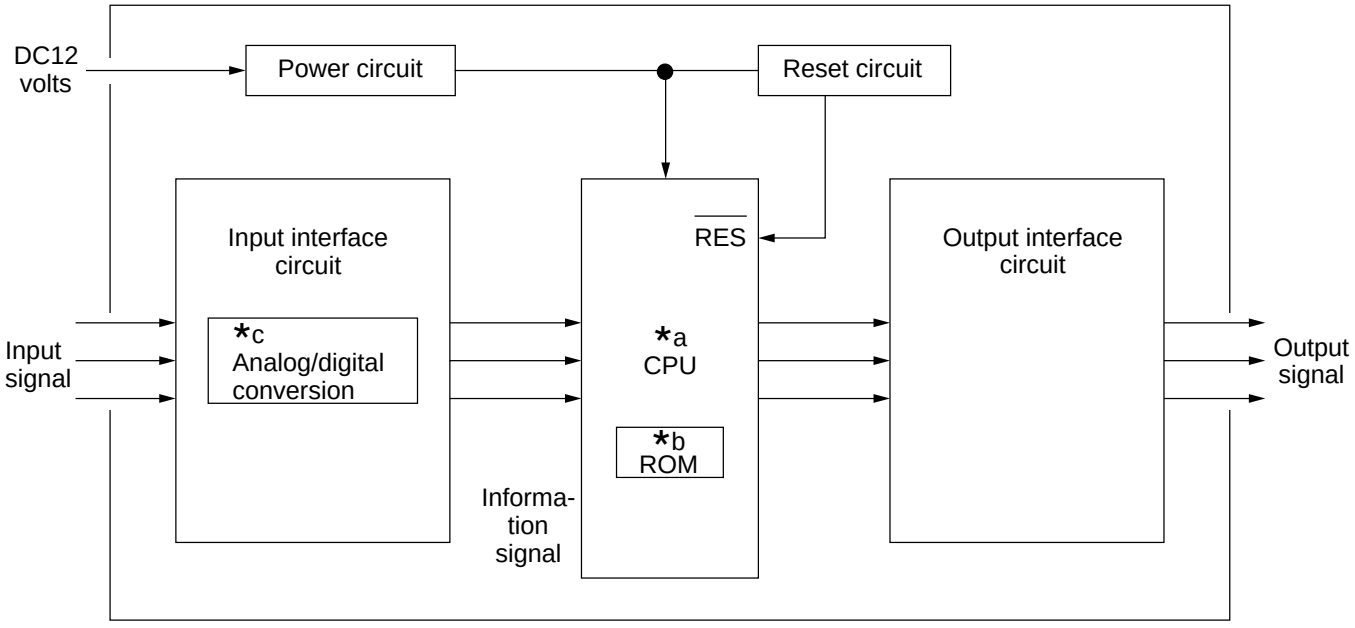
Preheating function	P54-0-20
Intermittent wiper activation function	Gr 42
Wiper activation function (Even if the wiper switch is OFF, this function automatically activates the wiper when the window washer works)	Gr 42
Water level warning function	Gr 14
Starter continuous-ON prevention function	P54-0-22

- For controlling each function, sensors and switches are needed as sources of information, and they are provided for respective systems.
- Based on the information provided by the sensors and switches, the MUTIC controls above functions by means of the circuits inside itself.

● **Internal structure of MUTIC**



- The MUTIC is internally made up roughly of the input interface circuit, CPU*a, ROM*b, and output interface circuit.
  *a: An abbreviation for Central Processing Unit. It compares the input information and the information stored in the ROM and makes a decision and sends commands to the outputs.
  *b: An abbreviation for Read-Only Memory. It is an element used exclusively to have its contents read. It stores fixed data and program, and such retained information is not deleted even after power is cut off.
- Information sources such as sensor, switch send input signal to the input interface circuit.
- The input interface circuit performs A/D conversion*c of the input signals, and the converted signals are transmitted to the CPU as information signals.
  *c: An abbreviation for Analog/Digital conversion. It is a conversion from analog to digital signals. This conversion enables calculation to be made in the CPU.
- The CPU compares the received signals with the data in the ROM, makes a decision, and sends the results to the output interface circuit.
- The output interface circuit transmits these results to each system as output signals to instruct operations.
- Performing these series of operations continuously enables optimum control of each function.

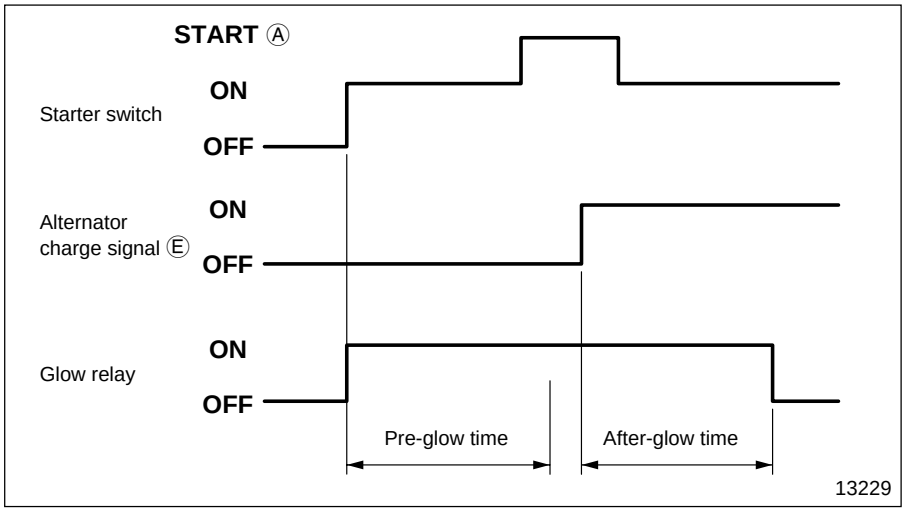
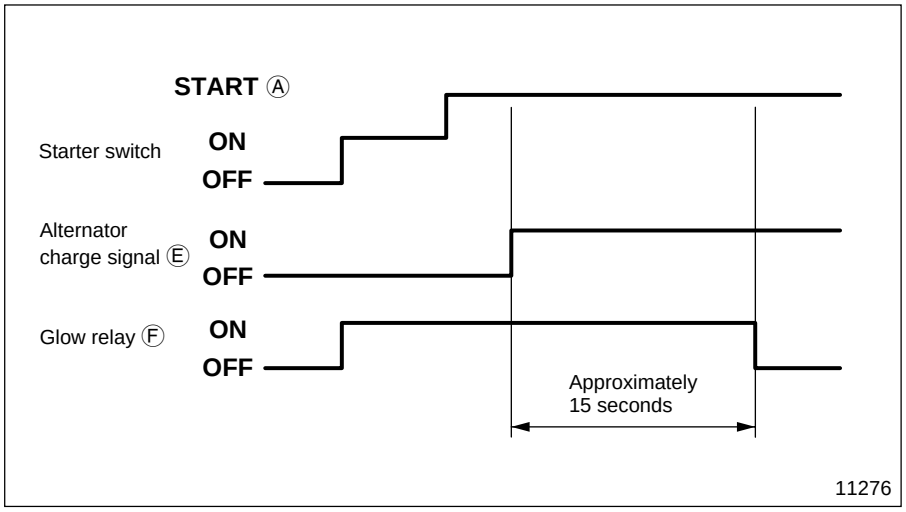
Preheating Function

This preheating function aims to enhance the engine start up when the engine coolant is low in cold weather or temperature.
MUTIC (Multipurpose Timing Control Unit) controls the entire function as follows:



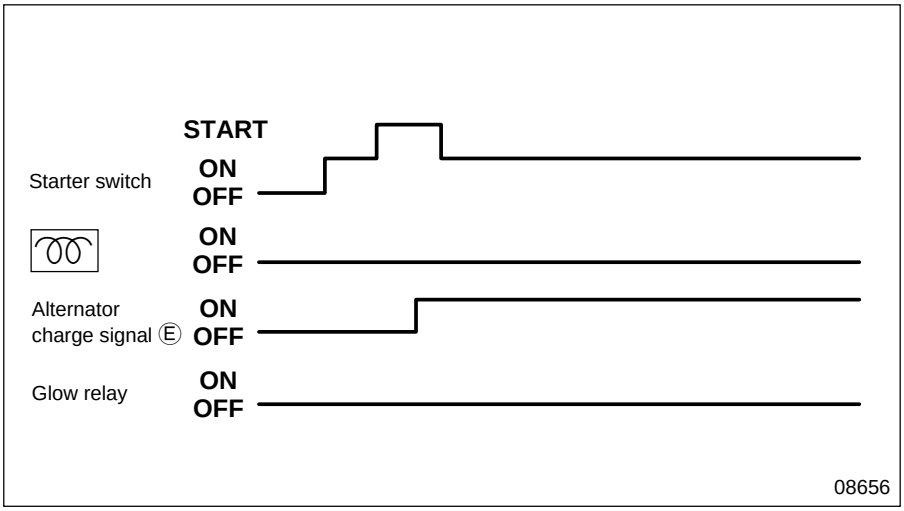
Pre-glow and After-glow

The preheating is operated with a pre-glow before the engine starting and an after-glow after the engine starting, which are controlled by the starter switch (S terminal) signal Ⓐ and the alternator (L terminal) signal Ⓔ.



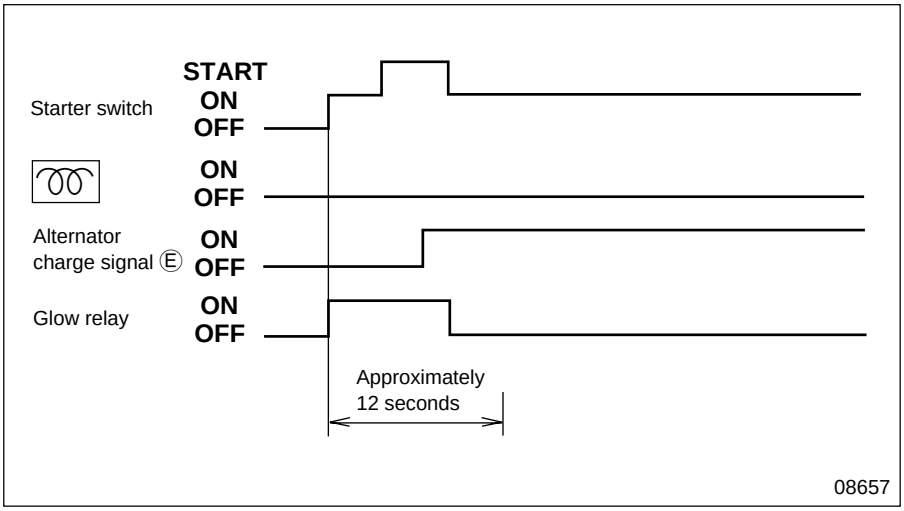
Fail Safe

- In case the contact point operating the glow relay in MUTIC has melted, the preheating indicator lamp flashes to warn this abnormality.
- Operation mode turns glow relay activation signal Ⓕ to OFF only after all the following conditions are met.
  - Where the engine coolant temperature is 60°C {140°F} or less.
  - Alternator (L terminal) signal Ⓔ is ON for 15 seconds continuously.
  - Starter switch (S terminal) signal Ⓐ is ON.

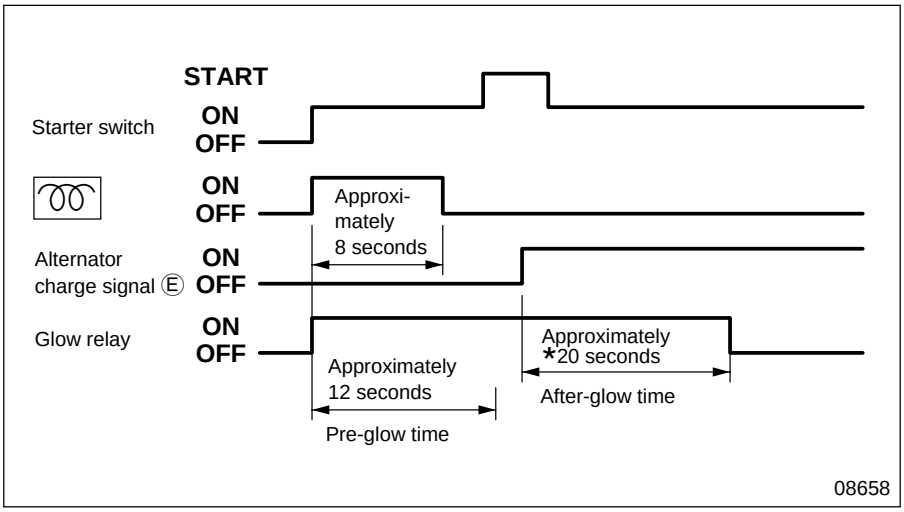


Operation mode

- Where the engine coolant temperature is 60°C {140°F} or more.



- Where the engine coolant temperature is 0 to 60°C {32 to 140°F}.
- Where the engine coolant temperature is aproximately 15 to 60°C {59 to 140°F} for production dated September 2002 onward.



- Where the engine coolant temperature is 0°C {32°F} or less.
- Where the engine coolant temperature is aproximately 15°C {59°F} or less for production dated September 2002 onward.

*: Approximately 180 seconds for production dated September 2002 onward.

Starter Continuous-ON Prevention Function

- This function prevents a starter overrun.
- If the starter continues to operate for more than a preset time after the engine starts, the MUTIC detects a starter continuous-ON condition, and stops the current to the starter and starter relay to prevent the starter from seizing.

When a preset time elapses after the engine starts, the safey relay is activated (opening of contact) by signal Ⓔ from the alternator (terminal L).

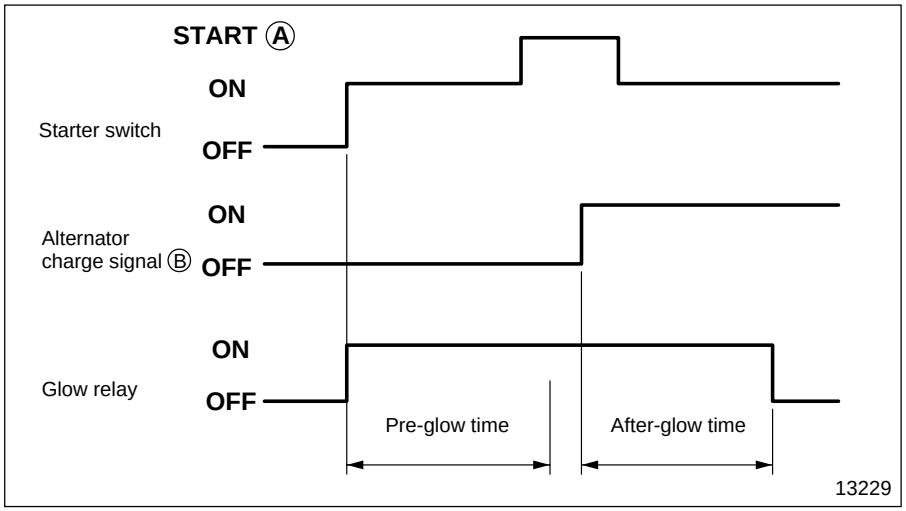
The operation of intermittent wiper is controlled by MUTIC in a mode as shown.

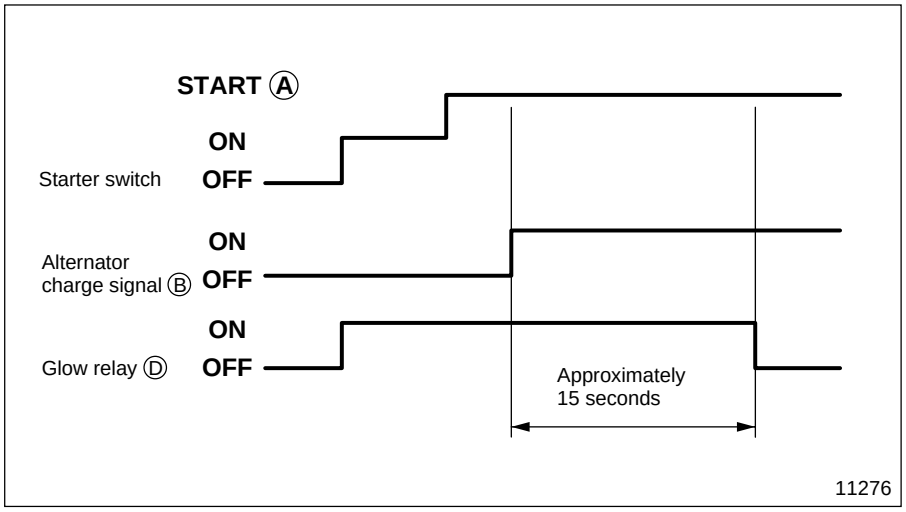
Preheating Function

This preheating function aims to enhance the engine start up when the engine coolant is low in cold weather or temperature.
MUTIC (Multipurpose Timing Control Unit) controls the entire function as follows:



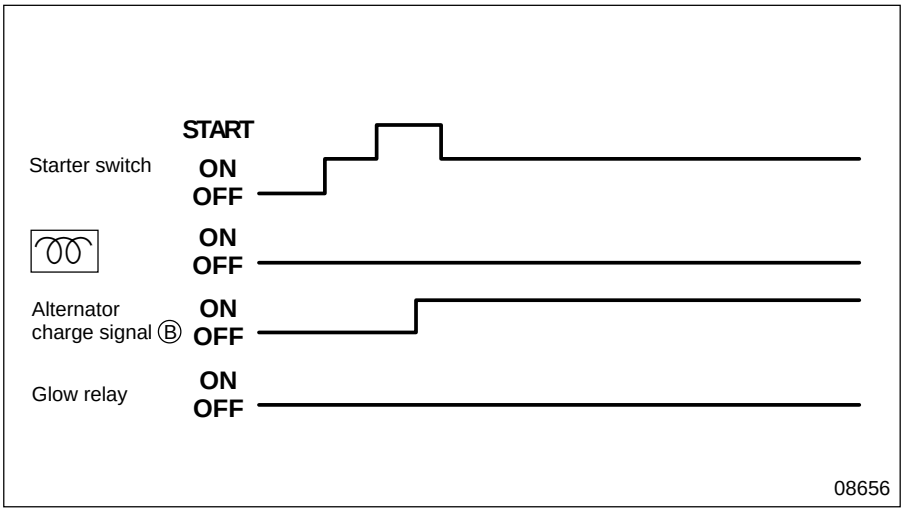
Pre-glow and After-glow

The preheating is operated with a pre-glow before the engine starting and an after-glow after the engine starting, which are controlled by the starter switch (S terminal) signal Ⓐ and the alternator (L terminal) signal Ⓑ.



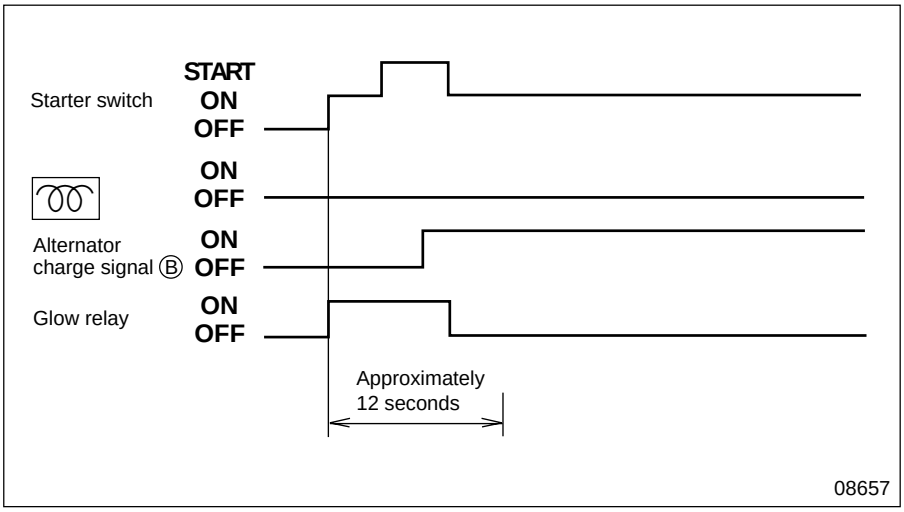
Fail Safe

- In case the contact point operating the glow relay in MUTIC has melted, the preheating indicator lamp flashes to warn this abnormality.
- Operation mode turns glow relay activation signal Ⓓ to OFF only after all the following conditions are met.
  - Where the engine coolant temperature is 60°C {140°F} or less.
  - Alternator (L terminal) signal Ⓑ is ON for 15 seconds continuously.
  - Starter switch (S terminal) signal Ⓐ is ON.

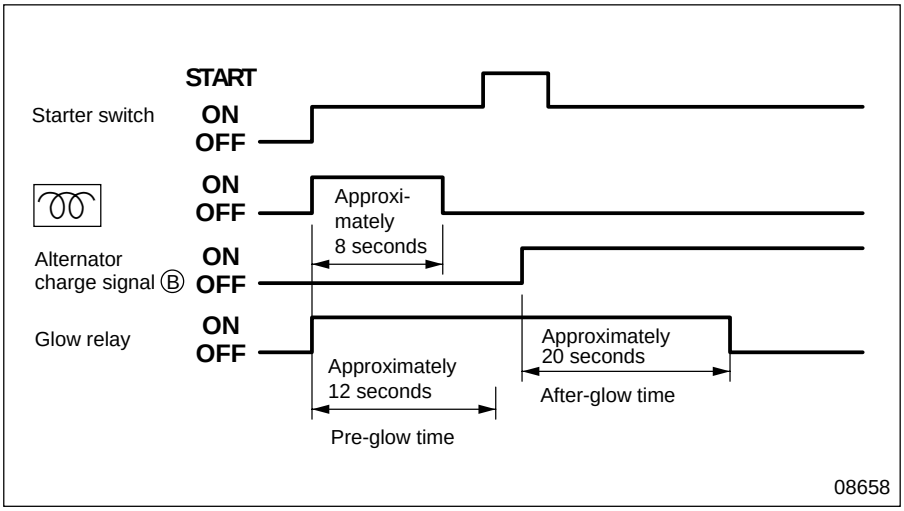


Operation mode

- Where the engine coolant temperature is 60°C {140°F} or more.



- Where the engine coolant temperature is 0 to 60°C {32 to 140°F}.



- Where the engine coolant temperature is 0°C {32°F} or less.

Starter Continuous-ON Prevention Function

- This function prevents a starter overrun.
- If the starter continues to operate for more than a preset time after the engine starts, the MUTIC detects a starter continuous-ON condition, and stops the current to the starter and starter relay to prevent the starter from seizing.

When a preset time elapses after the engine starts, the safey relay is activated (opening of contact) by signal Ⓑ from the alternator (terminal L).

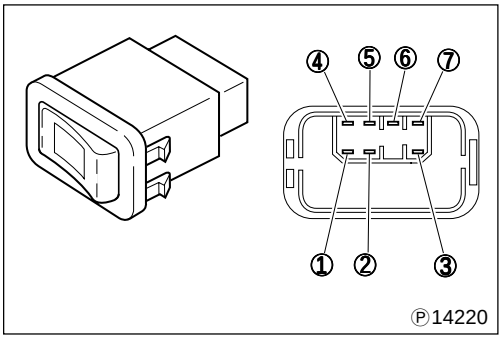
011 **Inspection of rheostat switch**

- Rheostat switch contains a control circuit, because of this it is difficult to inspect rheostat switch independently, therefore you should inspect the rheostat switch indirectly, by inspecting the system harness and the related parts.
- If no fault is found in the related parts but the system is faulty, replace the switch.



012 **Inspection of warm-up switch**

- Follow the table below to check for continuity.

○——○ : There is continuity between terminals.

- If any fault is found, replace the switch.

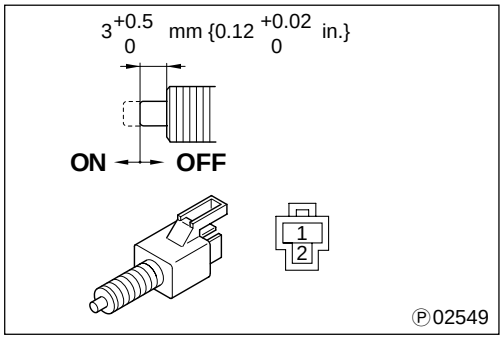
027 Inspection of power window switch, and power window and auto door lock switch

- Switches contains a control circuit, because of this it is difficult to inspect switches independently, therefore you should inspect the system harness, power window motor, door lock actuator etc. the related parts.
- If no fault is found in the related parts but the system is faulty, replace switches.



031 Inspection of clutch switch

○—○ : There is continuity between terminals.

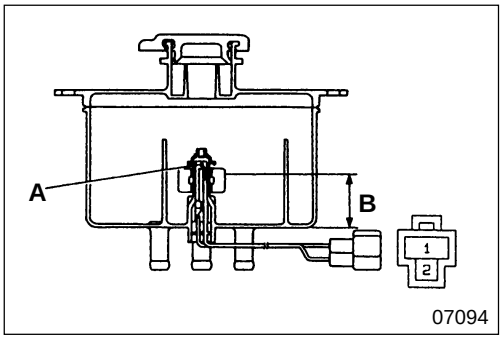
- If any fault is found, replace the switch. Gr 36



041 Inspection of brake fluid level switch

- Remove brake fluid slowly from fluid tank assembly.

CAUTION

If brake fluid gets on a painted surface it will dissolve the paint, so wipe it off immediately.

- Measure the height **B** of switch **A** when the continuity is detected between terminals ① and ②.

Standard value	41.0 ± 3 mm {1.61 ± 0.12 in.} (equivalent to 120cm³ {7.32 cu.in., 0.12L})

- If the measured value deviates from the standard value, replace the brake fluid tank assembly. Gr 42

044 Inspection of engine oil pressure switch

Perform the following checks, and if any fault is found, replace the switch.

(1) Inspection by without applying air pressure

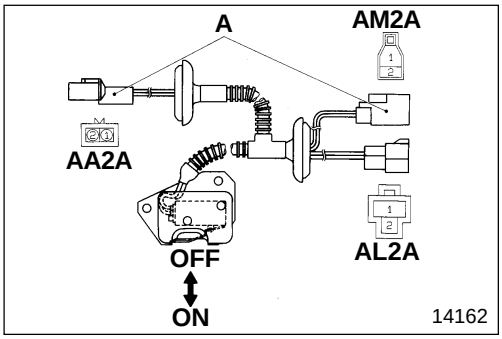
Make sure that there is continuity between terminals ① and ② (body).

(2) Inspection by applying air pressure

- Gradually apply air pressure **A** to the switch starting from 0 kPa {0 psi, 0 kgf/cm²}.
- Measure the degree of air pressure at the moment when continuity is not detected between terminals ① and ② (body), and make sure to confirm if the value meets the standard.

B : Air pressure gauge

Standard value (operating pressure)	49 ± 9.8 kPa {7.1 ± 1.4 psi, 0.5 ± 0.1 kgf/cm²}



045 Inspection of cab tilt lock switch

- Follow the table below to check for continuity.

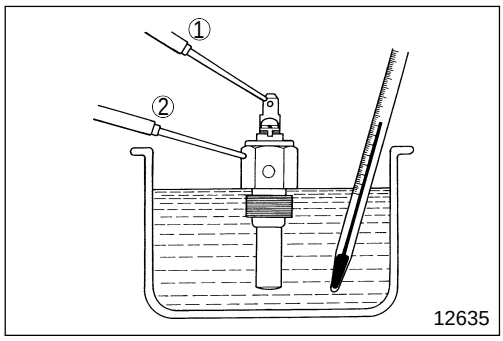
ON	○	○	○	—⧸\/\/\—▷—	○
OFF					

○—○ : There is continuity between terminals.

- If any fault is found, replace the switch.



160 Inspection of overheating switch

- Place the switch in engine oil in a container.
- Raise the oil temperature to the specified values and stir the oil.
- Measure the operating temperature between terminals ① and ② (body) respectively.

Standard Value	When temperature increase (ON→OFF)	110±2°C {230±36°F}
	When temperature decrease (OFF→ON)	110°C±4°C {230±39°F}

- If the measured value deviates from the standard value, replace the switch. Gr 14

195 Inspection of glow relay

(1) Inspection of fuse

If any fault is found, replace the fuse **A** (127 ampere).

(2) Inspection of main body

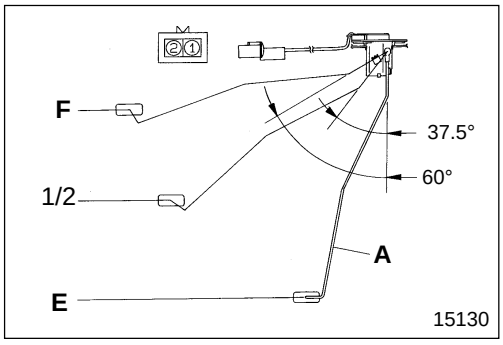
- Follow the table below to check for continuity and operation.

	①	②	③	④	⑤ (Body)
OFF	○——○			○——○	
ON	○——○——○			⊕——⊖	

○——○ : There is continuity between terminals.

⊕——⊖ : Indicates the terminals where battery voltage is to be applied.

- If any fault is found, replace the relay.



258 Inspection of fuel level sensor

- Measure the resistance between terminals ① and ② when float arm **A** contacts to both stoppers (positions **E** and **F**) and also 1/2 position.

Standard value	F (FULL position)	$0\ ^{+2}_{0}\ \Omega$
	1/2	50 ± 3 Ω
	E (EMPTY position)	150 ± 10 Ω

- If the measured value deviates from the standard value, replace the sensor. Gr 13

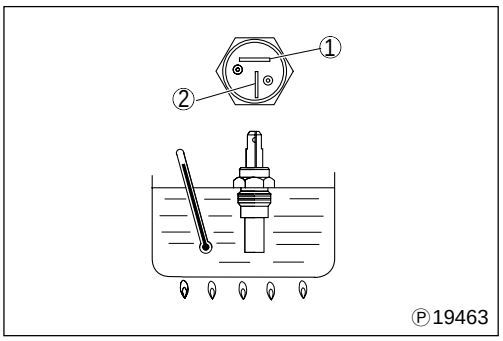
○——○ : There is continuity between terminals.

- If any fault is found, replace the sensor. Gr 14

A : Engine coolant



262 Inspection of water temperature sensor

< For multipurpose timing control unit >

- Place the sensor in engine oil in a container.
- Raise the oil temperature to the specified values and stir the oil.
- Measure the resistance between terminals ① and ②, and the body respectively.
  Terminal ① : Water temperature gauge connection
  Terminal ② : Multipurpose timing control unit connection

Standard Value	①—Body (connection side of water temperature sensor)	50°C {122°F}	153.9 Ω (Reference value)
		80°C {176°F}	$51.9\ ^{+4.9}_{-4.4}\ \Omega$

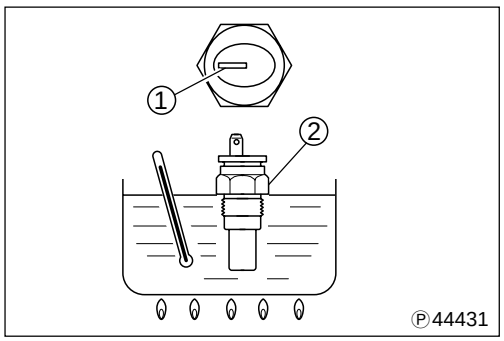
		60°C {140°F}	620 Ω (Reference value)
		80°C {176°F}	300 Ω (Reference value)

- If the measured value deviates from the standard value, replace the sensor. Gr 14

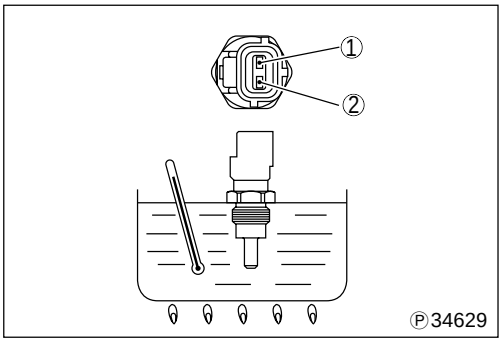


< For engine control (6D3)>

- Place the sensor in engine oil in a container.
- Raise the oil temperature to the specified values and stir the oil.
- Measure the resistance between terminals ① and ② (body).

Standard value	20°C {68°F}	3.25 kΩ (Reference value)
	60°C {140°F}	620±62 Ω
	80°C {176°F}	300 Ω (Reference value)

- If the measured value deviates from the standard value, replace the sensor. Gr 14

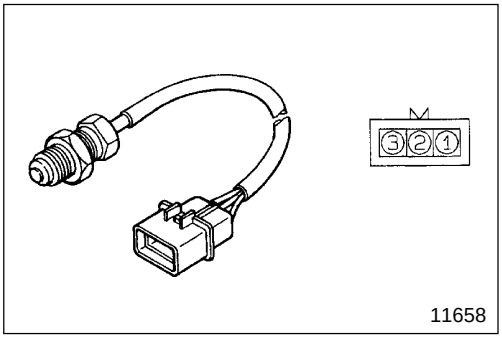


< For engine control (4M5)>

- Place the sensor in engine oil in a container.
- Raise the oil temperature to the specified values and stir the oil.
- Measure the resistance between terminals ① and ②.

Standard value	20°C {68°F}	2.3 to 2.6 kΩ
	80°C {176°F}	0.30 to 0.34 kΩ

- If the measured value deviates from the standard value, replace the sensor. Gr 14



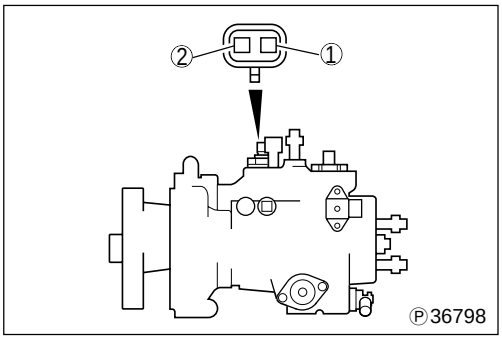
263 Inspection of engine speed sensor

< 6D3 >

- Measure the resistance between terminals ① and ②.

Standard value (at 25°C {77°F})	2.1 to 2.5 kΩ

- If the measured value deviates from the standard value, replace the sensor.



< 4M5 >

- Measure the resistance between terminals ① and ②.

Standard value (at 20°C {68°F})	230 ± 25 Ω

- If the measured value deviates from the standard value, replace the sensor.

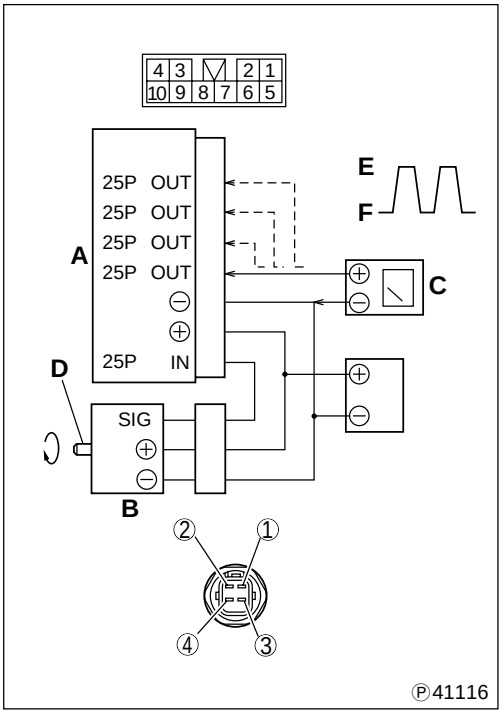
350 Inspection of control units and other units

- Since the units alone cannot be readily checked in the off-vehicle state, check the harness, switch and other related parts in each system.
- If any fault is not found in the related parts, and the problem still remains in the system, replace the control units or other units.



351 Inspection of Pulse Divider

Perform the following checks, and if any fault is found, replace the pulse divider.

- Wire the pulse divider **A** as shown.
  B: Vehicle speed sensor (Use 25-pulse terminals.)
  C: Tester
- Slowly rotate the shaft **D** of the vehicle speed sensor **B** by hand and measure the maximum value (high pulse voltage **E**) and the min imum value (low pulse voltage **F**) of the voltage generated across each of the output terminals (③, ④, ⑨, ⑩) and terminal ⑧ of the pulse divider **A**.

Standard value	Low pulse voltage **F**	0.6 V or less
	High pulse voltage **E**	8 ± 1 V

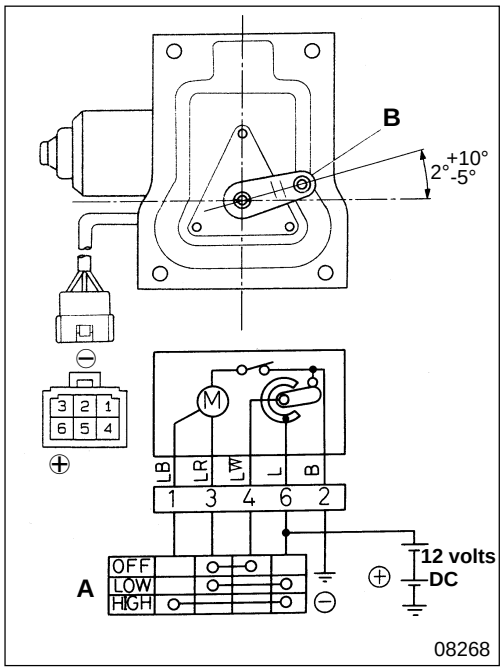
411 Inspection of blower motor

- Make sure that the motor operates when battery voltage is applied between terminals ① and ②.
- If any fault is found, replace the motor. Gr 55



422 Inspection of wiper motor

- Connect a switch to the motor as shown.

  A : Switch

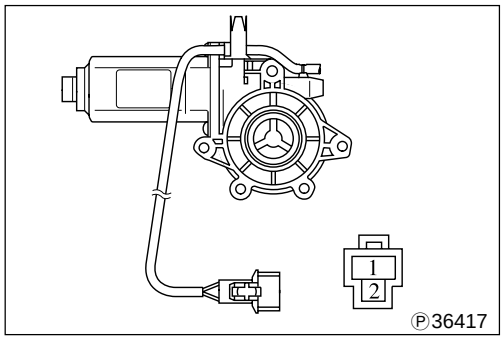
- Check the motor for correct operation as follows. If any fault is found, replace the motor. Gr 42

(1) Inspection of motor operation

- Set switch **A** in HIGH position to check that the motor rotates at high speed.
- Set switch **A** in LOW position to check that the motor rotates at low speed.

(2) Inspection of automatic stop position

- Set switch **A** in LOW position to let the motor rotates at low speed.
- When crank arm **B** is at a position other than the automatic stop position (outside the angles shown), set switch **A** in OFF position.
- Check to see the crank arm **B** stops at the automatic stop position (within the angles range shown).



423 Inspection of power window motor

- Follow the table below to check for operation.

	①	②
UP	⊕	⊖
DOWN	⊖	⊕

⊕——⊖: Indicates the terminals where battery voltage is to be applied.

- If any fault is found, replace the motor. Gr 42

565 Inspection of exhaust brake 3-way magnetic valve <FH210>

Perform the following checks, and if any fault is found, replace the 3-way magnetic valve.

(1) Operation test

- Gradually apply battery voltage to between terminals ① and ② from 0 volt.
- Measure the voltage (minimum operating voltage) at the moment when the 3-way magnetic valves starts operating. (The OFF to ON operating can be noticed from a sound the magnetic valve generates.)

Standard value (Minimum operating voltage)	11V or less

(2) Continuity and airtightness test

Follow the table below to check for continuity.

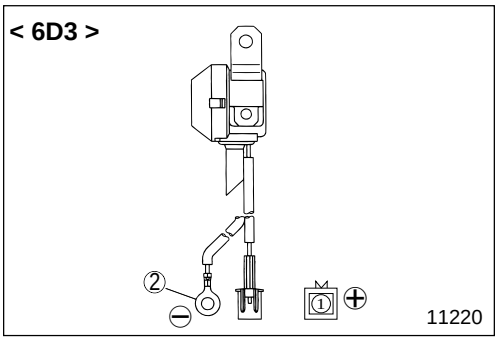
611 Inspection of warning buzzer

- Make sure that the buzzer sounds when battery voltage is applied between terminals ① and ②.
- If any fault is found, replace the buzzer.

< 6D3 >

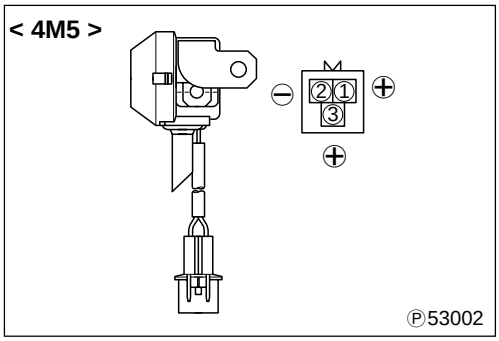


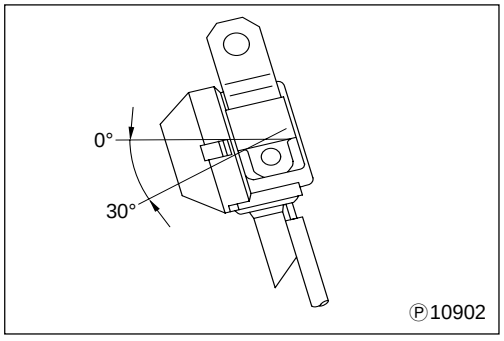
614 Back buzzer

[Inspection]

- Make sure that the buzzer sounds intermittently when battery voltage is applied between terminals ① and ②.
- If any fault is found, replace the buzzer.

< 4M5 >





[Installation]

Attach the buzzer to the frame at an angle within the range shown.

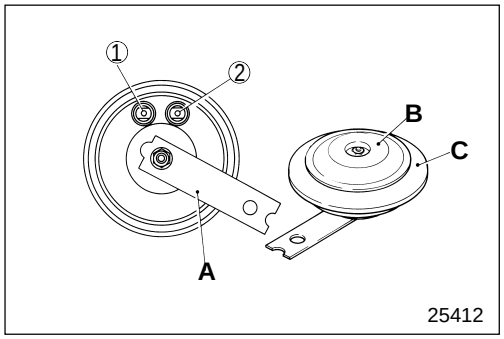
CAUTION⚠

Be careful to install the buzzer within the illustrated angle range or the buzzer will not be drained normally.

615 Inspection of electric horn

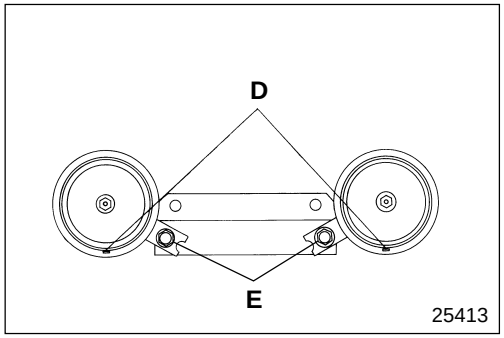
CAUTION⚠

Do not bend or damage stay A or the sound quality of electric horn may be changed and the horn capacity can deteriorate.



[Inspection]

- Apply battery voltage between terminals ① and ② (No polarity) to make sure that the horn sounds.
- If any fault is found, replace the horn.
- Remove foreign particles from resonator **B** or vibration plate **C**, if any.



[Installation]

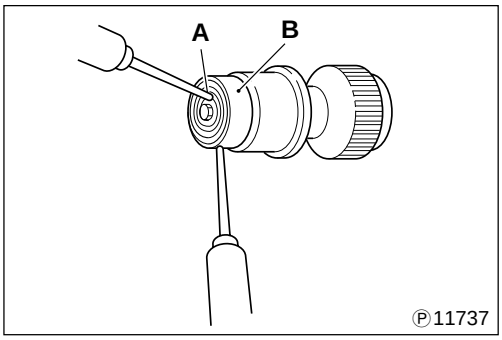
- Follow the table below to check for resistance of between terminals.

Standard value	MIDDLE LOW	①—②	0.81 Ω
	MIDDLE HIGH	①—③	0.28 Ω
	LOW	①—④	1.94 Ω

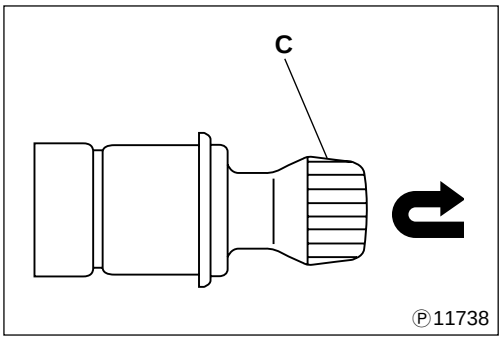
- If the measured value deviates from the standard value, replace the blower resistor.



754 Inspection of cigarette lighter

Perform the following checks, and if any fault is found, replace the cigarette lighter.

- Make sure that there is continuity between heater element **A** and body **B**.



- Make sure that when plug **C** is pushed in by hand, it immediately returns to its original position.
- Turn the starter switch at ACC or ON position.
- Push plug **C** into the socket in the cab.
- Measure the time required for plug **C** automatically returns.

Standard value	15 ± 5 seconds

- Check to see that heater element **A** is red-hot.

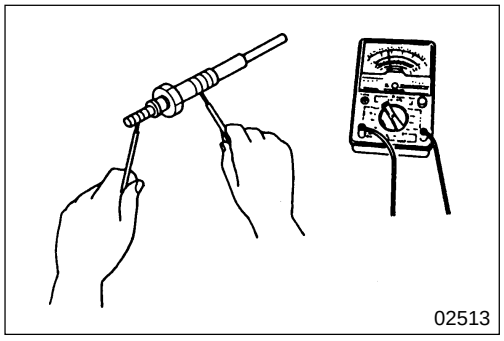
- If any fault is found, replace the switch **A** or heater control assembly.
- If the illumination lamp has blown out, replace the bulb.



764 Inspection of glow plug

- Measure the resistance of glow plug as shown.

Standard value (Cold resistance of glow plug)	4M5	1.0 Ω (Reference value)
	6D3	0.6 Ω (Reference value)

- If the measured value deviates from the standard value, replace the glow plug. Gr 11

DANGER⚠

- **Because flammable hydrogen gas is generated from battery, be sure to obey the following:**
  - **Never attempt to short-circuit the positive and negative terminals of battery, and generate sparks, or smoke a cigarette near it.**
  - **Do not wear metal objects on your arms or do not lean over battery.**
- **Sulfuric acid of the electrolyte is very corrosive. Whenever handling battery, wear safety goggles and rubber gloves to protect your eyes and hands.**
- **Battery posts, terminals and related accessories contain lead and lead compounds. Wash hands after handling.**

WARNING⚠

- **When you disconnect battery cables, disconnect the negative battery cable ⊖ first.**

CAUTION⚠

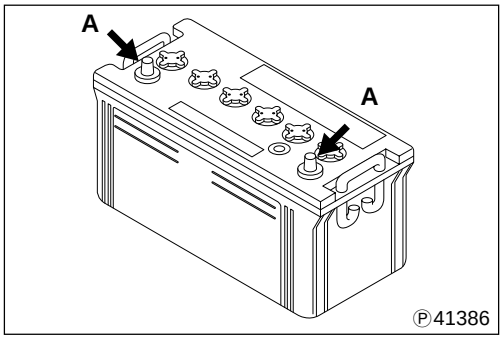
- **Make sure that all electrical switches of the vehicle are off before connecting battery cables.**
- **Be sure to connect the positive battery cable ⊕ first before you connect the negative battery cable ⊖.**
- **To prevent a short-circuit, take care that disconnected battery cables may not accidentally touch the battery terminals.**

Service standards

Location	Maintenance item	Standard value	Limit	Remedy
—	Specific gravity of battery electrolyte (20°C {68°F})	1.220 to 1.290	—	Charge or replace

◆ Service procedure

Inspection of battery

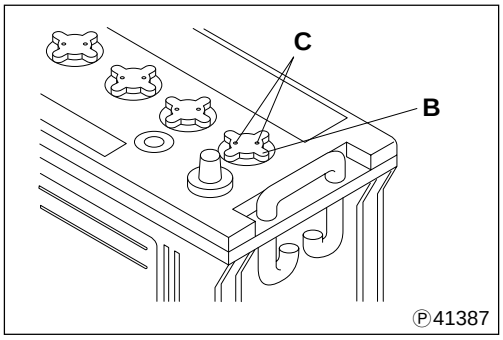


(1) Visual inspection

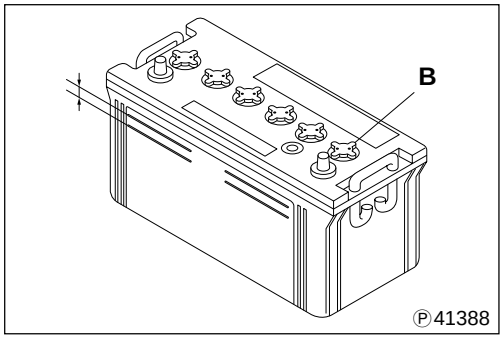
- If terminal **A** is corroded, scrub off the corrosion from it using a wire brush.
- If cracks or defects are found on battery, replace it since the cracks or defects can cause liquid spills.

CAUTION⚠

Make sure you grease the ⊕ side of terminal A because it is easily corroded.

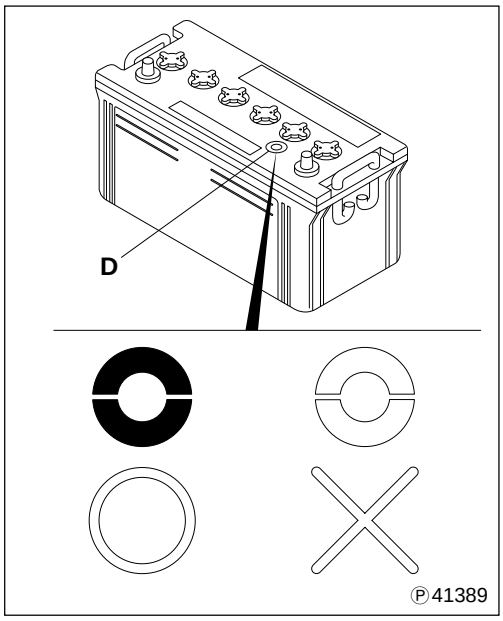


- If bleed hole **C** of vent plug **B** is clogged, clean the hole.



(2) Inspection of fluid level

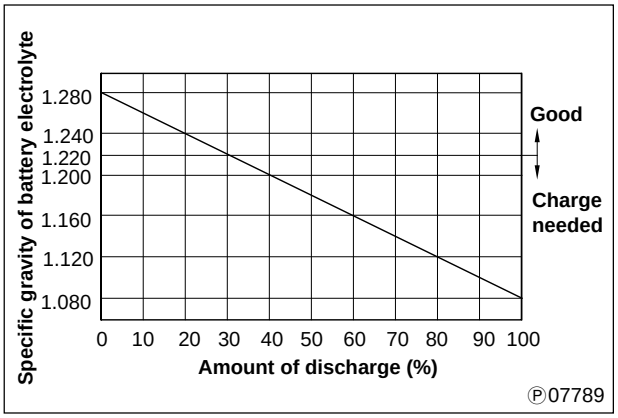
- Make sure that the battery electrolyte level is between UPPER and LOWER.
- If the level is below LOWER, remove vent plug **B** and fill the battery with distilled water or battery replenisher to UPPER.



(3) Measurement of specific gravity

You can tell the specific gravity of the battery electrolyte by the color shown in indicator **D**.

Blue : Good
White : Charge or replace



(4) Charging

- Although, as a rule, battery charging should be done with the battery removed from the vehicle, if you have to charge the battery while it is on the vehicle, make sure that you stop the engine and disconnect battery cable ⊖.
- Remove vent plug before charging the battery.
- For the recommended charge time and current, see the following table to avoid overcharging.

	Charge current (A)	Charge time (H)	Upper limit of fluid temperature (°C {°F})
Normal charge	$\frac{\text{Value of 5-hour rating capacity}}{10}$	$\frac{\text{*Amount of discharge (Ah)}}{\text{Charge current (A)}} \times 1.2$ (to 1.5)	45 {113}
Quick charge	$\frac{\text{Value of 5-hour rating capacity}}{1.5}$	0.5	55 {131}

* Amount of discharge (Ah)=5-hour rating capacity (Ah) $\times \frac{\text{Amount of discharge (\%)}}{100}$

- Use the graph shown on the left to calculate the amount of discharge (%).
- Use diluted sulfuric acid, made up of sulfuric acid and refined or distilled water, as the battery electrolyte.
- The specific gravity of fully-charged battery electrolyte is 1.280 with the temperature at 20°C {68°F}.

DANGER⚠

- **Do not let the battery electrolyte level rise and overflow while charging the battery.**
- **Keep open flame away from the battery while charging it or it might explode.**
- **Be careful not to generate sparks while charging the battery because it is dangerous.**
- **After charging the battery, tighten the vent plugs, wash away sulfuric acid from the battery using water, and dry the surface.**
- **Be sure to check the electrolyte level before charging the battery. Charging with the electrolyte level below the lower limit (LOWER LEVEL) can cause premature deterioration, heat generation and explosion of the battery.**

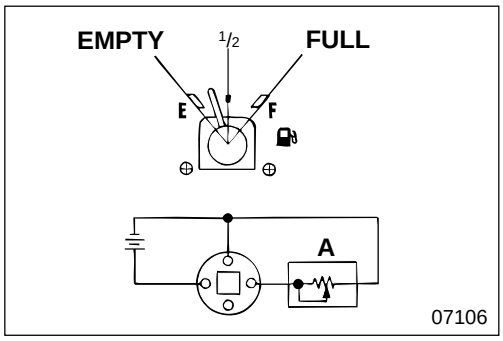
3 Inspection of speedometer

- Use the speedometer tester to check that the indication area of speedometer **3** does not deviate from the standard value at each speed.
- If the measured value deviates from the standard value, replace the speedometer.



4 Inspection of fuel gauge

- Connect a variable resistor to fuel gauge **4** as shown.
  A : Variable resistor
- Measurement order
  FULL → 1/2 → EMPTY

NOTE

The movement of the gauge needle is subject to hysteresis (oscillation). Be sure to measure following the measurement order.

- Increase the value of variable resistor **A** gradually from 0 Ω.
- Measure the resistance respectively when the needle of fuel gauge **4** indicates FULL, 1/2, and EMPTY.
- If the measured value deviates from the standard value, replace fuel gauge **4**.

- Connect a variable resistor to water temperature gauge **5** as shown.
  A : Variable resistor
- Measurement order
  65°C {149°F}→ 100°C {212°F}

NOTE

The movement of the gauge needle is subject to hysteresis (oscillation). Be sure to measure following the measurement order.

- Increase the value of variable resistor **A** gradually from 0 Ω.
- Measure the resistance respectively when the needle of water temperature gauge **5** indicates 65°C {149°F}, and 100°C {212°F}.
- If the measured value deviates from the standard value, replace water temperature gauge **5**.

- Connect a variable resistor to water temperature gauge **5** as shown.
  A : Variable resistor
- Measurement order
  50°C {122°F}→ 120°C {248°F}

NOTE

The movement of the gauge needle is subject to hysteresis (oscillation). Be sure to measure following the measurement order.

- Increase the value of variable resistor **A** gradually from 0 Ω.
- Measure the resistance respectively when the needle of water temperature gauge **5** indicates 50°C {122°F}, 83°C {181°F} to 105°C {189°F}, and 120°C {248°F}.
- If the measured value deviates from the standard value, replace water temperature gauge **5**.

6 Inspection of tachometer

- Use the engine revolution counter to check that the indication area of tachometer **6** is in the standard value at each revolution.
- If the measured value deviates from the standard value, replace tachometer **6.**

◆ Service procedure

● Inspection after assembly

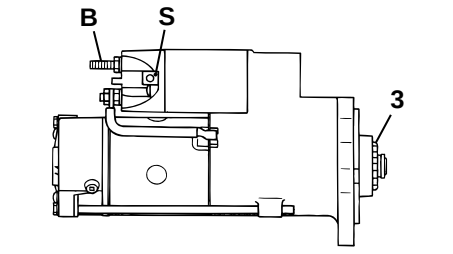
Inspection after assembling the starter should be carried out with current fed to the starter.

WARNING⚠

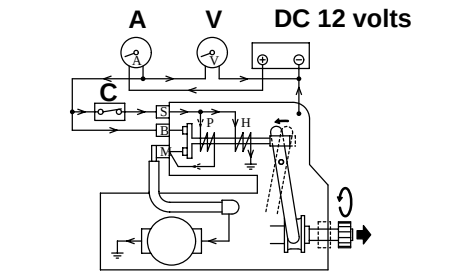
- **Do not touch pinion 3 because it jumps out and turns when current is fed to the starter.**
- **Take care not to burn your hand, magnetic switch assembly 5 might be hot during inspection.**

CAUTION⚠

- **The current feeding time to the starter should be within 10 seconds at pull-in coil P side and within 30 seconds at holding coil H side. If the current feeding time exceeds these limits the coil might burn due to overheating.**
- **The current, when fed to the starter, is over 100 amperes. When inspecting, use thick cable, such as a booster cable, and make secure connections.**



13296



Ⓟ14258

(1) Performance test

- Connect the starter as shown.
  A : Ammeter
  B : Terminal B of starter
  C : Switch
  S : Terminal S of starter
  V : Voltmeter
- Set the voltage to 11 volts DC.

CAUTION⚠

Up to 12 volts can be loaded.

- The following work should be done with current fed to the starter. You must complete measurement of the current and the number of revolutions within 30 seconds.
  - Turn switch **C** ON and feed current to the starter. In this state, pinion **3** jumps out and rotates.

CAUTION⚠

When switch C is turned ON, current is fed both to pull-in coil P and holding coil H. When a large amount of current is fed into terminal M from DC 12 volts, via terminal B of the starter, the current stops flowing into the pull-in coil but continues to flow into the holding coil.

To avoid burning the holding coil, be sure to carry out the performance test within 30 seconds.

  - Measure the current and the number of revolutions of the starter. Train a strobe light on pinion **3** to measure the number of revolutions.
  - Turn switch **C** OFF to stop current to the starter.
- If the measured value deviates from the standard value, disassemble the starter again and inspect it.

- The following work should be done with current fed to the starter. You must complete measurement of the pinion gap within 30 seconds.
  - Turn switches **C** and **E** ON and feed current to the starter. In this state, pinion **3** jumps out and rotates.

  - Within 5 seconds of pinion **3** rotating, turn switch **E** OFF to stop rotation of the pinion.

CAUTION⚠

When switches C and E are turned ON, current is fed both to pull-in coil P and holding coil H. The circuit is wired in such a way that the voltage is not applied to terminal B of the starter, so the current continues to flow into the pull-in coil while pinion 3 rotates.
To avoid burning the pull-in coil, be sure to turn switch E OFF within 5 seconds of the pinion rotating.

  - Hold the end of overrunning clutch **33** with fingers, and pull it. Measure the distance **G** (pinion gap) in the shaft direction that the overrunning clutch moves when it is lightly pushed back by hand.

WARNING⚠

- **Do not touch pinion 3 because it jumps out and turns when current is fed to the starter.**
- **Take care not to burn your hand, magnetic switch assembly 5 might be hot after inspection.**

CAUTION⚠

- **The current feeding time to the starter should be within 10 seconds at pull-in coil P side and within 30 seconds at holding coil H side. If the current feeding time exceeds these limits, the coil might burn due to overheating.**
- **Before making pinion 3 jump out, be sure to feed current to the starter to obtain the correct state. If current is not fed to the starter and lever 36 is pulled to protrude the pinion, front bracket 39 or the lever might be damaged due to the shock produced on removal of stopper ring 1.**
- **The current, when fed to the starter, is over 100 amperes. When inspecting, use thick cable, such as a booster cable, and make secure connections.**

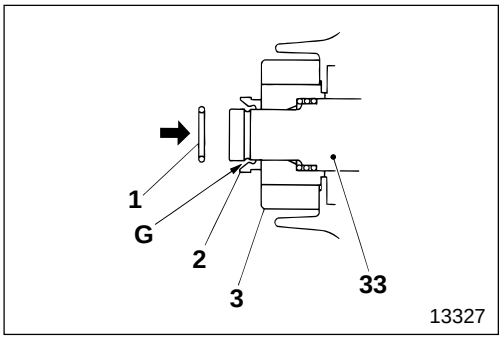
To avoid burning pull-in coil P, be sure to turn switch C OFF within 5 seconds after the pinion rotates.

- Apply pipe-shaped tool **E** onto pinion stopper **2**.
- Hit tool **E** lightly using a mallet to remove stopper ring **1** from ring groove **F** of pinion stopper **2**.
- Remove stopper ring **1** and pinion **3**.
- Turn switch **A** OFF to stop current to the starter.

NOTE

When the current to the starter is stopped, stopper ring 1 might fall back into ring groove F of pinion stopper 2 because pinion 3 is pushed inside.

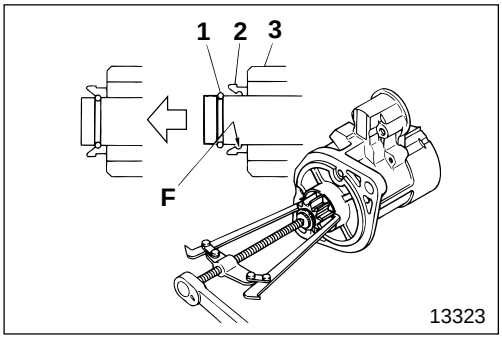
If this occurs, feed current to the starter again and carry out the work.



[Installation]

When installing pinion **3**, it is not necessary to feed current to the starter.

- Install pinion stopper **2** and pinion **3** onto overrunning clutch **33** in the direction as shown.
- Fit stopper ring **1** into ring groove **G** of overrunning clutch **33**.



- Pull pinion **3** firmly and set stopper ring **1** on groove **F** of pinion stopper **2** securely.

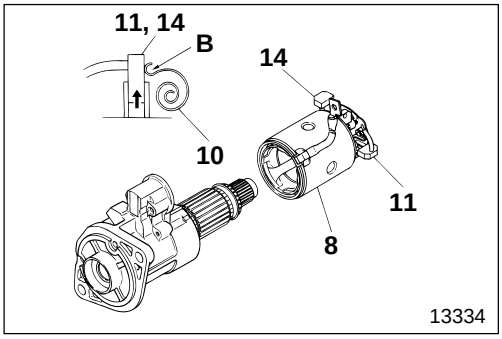
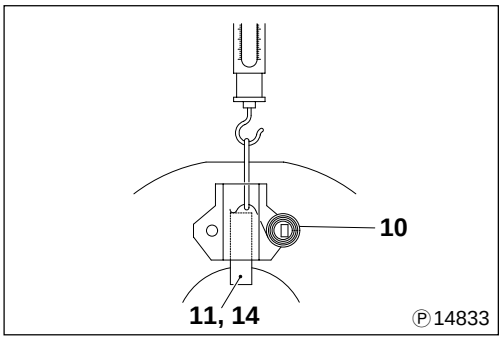
8 **Removal and installation of yoke and brush holder assembly**

Use the following method to remove the yoke and brush holder assembly **8** in order to prevent the commutator **A** of the armature assembly **16** from being damaged by the brushes **11** and **14**.

- Lift the brushes **11** and **14** away from the commutator **A** and hold them lifted by applying the brush springs **10** against the sides of the brush springs.

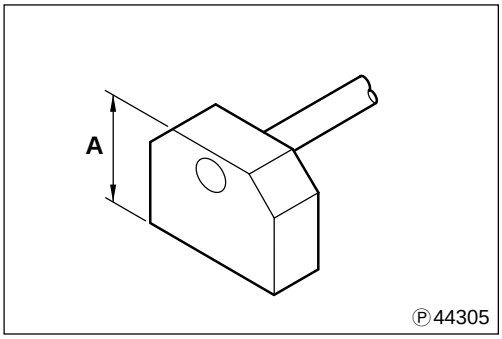


- Pull part **B** of each brush spring **10** and pull up the brushes **11** and **14**.
- Hold the brushes **11** and **14** in position with brush spring **10** as shown.
- Remove yoke and brush holder assembly **8**.
- To reinstall the yoke and brush holder assembly **8**, follow the removal instructions in, reverse.



10 **Inspection of brush spring**

- Use new brushes **11, 14** and measure the load when brush spring **10** is detached from the brushes.
- If the measured value is lower than the limit, replace brush spring **10**.



11 **14** **Inspection of brush**

(1) Length of brush

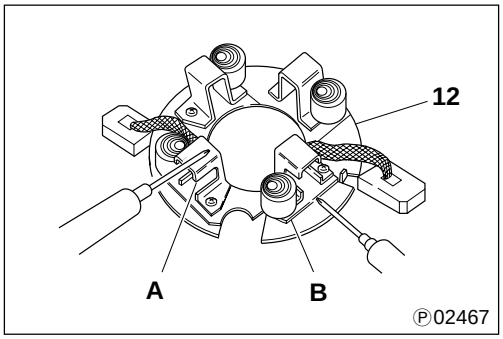
If the measured value **A** is lower than the limit, replace brushes **11, 14**.

NOTE

To replace brush ⊖ 11, replace entire brush holder assembly 12.

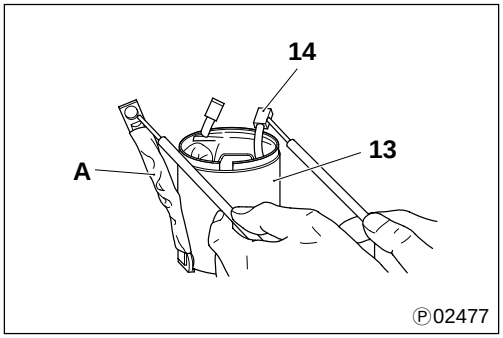
(2) Contact surface with commutator

If the surface where the brushes contact the commutator is rough or is worn unevenly, polish the surface with emery paper (300 to 500 grit).



12 Inspection of brush holder assembly

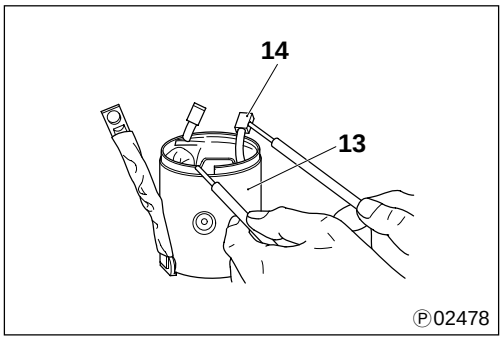
- Cleaning the brush holder **A** and holder plate **B**.
- Make sure that there is no continuity between the ⊕ side of the brush holder **A** and the ⊖ side of the holder plate **B**.
- If there is continuity between them, they are short-circuited. Replace brush holder assembly **12**.



13 Inspection of yoke assembly

(1) Testing for coil breakage

- Make sure that there is continuity between cable **A** and brush ⊕ **14**.
- If there is no continuity, they are broken. Replace brush ⊕ **14** or yoke assembly **13**.

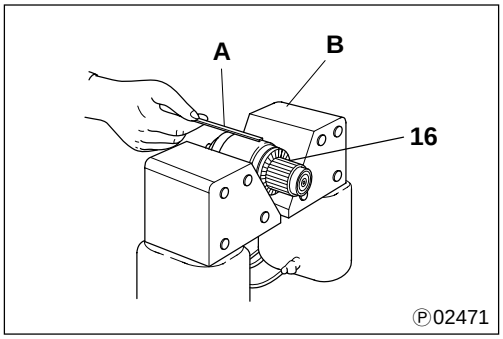


(2) Testing for coil grounding

- Make sure that there is no continuity between yoke assembly **13** and brush ⊕ **14**.
- If there is continuity, they are short-circuited. Inspect the insulated point. If it is hard to repair, replace brush ⊕ **14** or yoke assembly **13**.

NOTE

The coil may be short-circuited to the yoke assembly 13 due to the accumulation of worn-off metal particles from the brushes and/or armature.



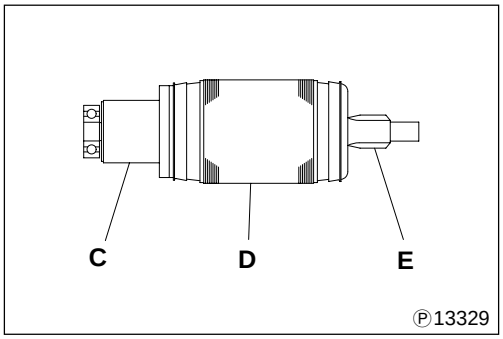
16 Inspection of armature assembly

(1) Testing for coil short-circuit

- Hold an iron rod **A** parallel with the armature assembly **16**.

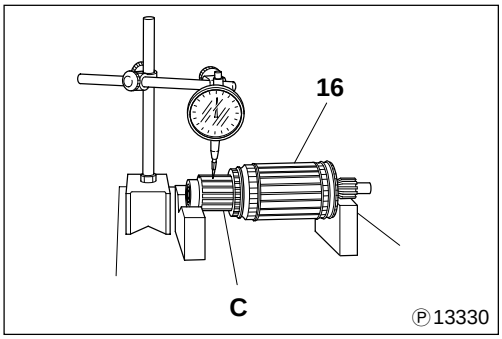
B : Armature tester

- Slowly rotate the armature assembly **16** by hand.
- If the iron rod **A** vibrates or is pulled toward the armature assembly **16**, the coil is short-circuited and the armature assembly must be replaced.



(2) Testing for coil grounding

- Make sure that there is no continuity between commutator **C** and core **D** (or shaft **E**).
- If there is continuity between them, they are short-circuited. Replace armature assembly **16**.

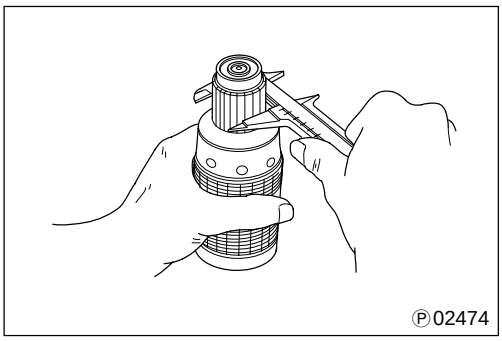


(3) Deflection of commutator

If the measured value is higher than the limit, correct the outer diameter of commutator **C** within the limit.

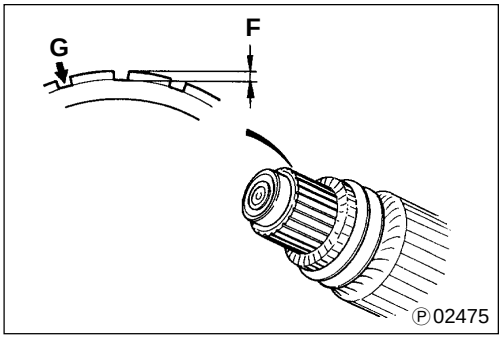
(4) Condition of the surface of commutator

- If the surface is rough or has stepped wear, polish the surface with emery paper (300 to 500 grit).
- After polishing, check deflection of commutator **C**.



(5) Outer diameter of commutator

If the measured value is higher than the limit, replace armature assembly **16**.



(6) Mold depth between segments

- If the measured value is lower than the limit, replace armature assembly **16**.

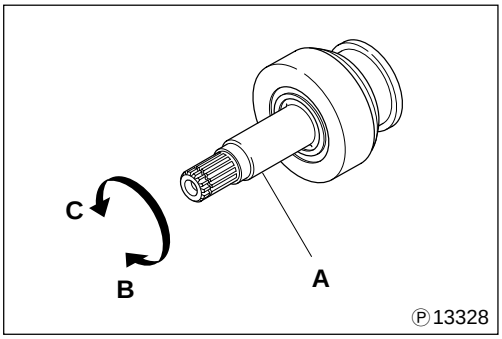
29 Removal of gear shaft and internal gear assembly

Remove the E-rings **28** and then the gear shaft and internal gear assembly **29** from the overrunning clutch **33**.
Proceed as follows if the gear shaft and internal gear assembly **29** cannot be removed due to interference of the splined section **A** of gear shaft assembly **30** with internal parts of the overrunning clutch **33**.

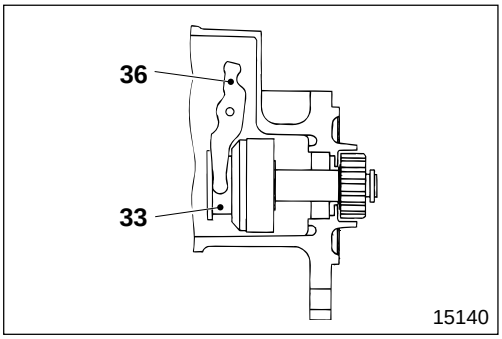
- Press the gear shaft assembly **30** against the overrunning clutch **33**.
- Turn the gear shaft assembly **30** approx. 1/8 of a turn to change the position of splined section **A**.



33 Inspection of overrunning clutch

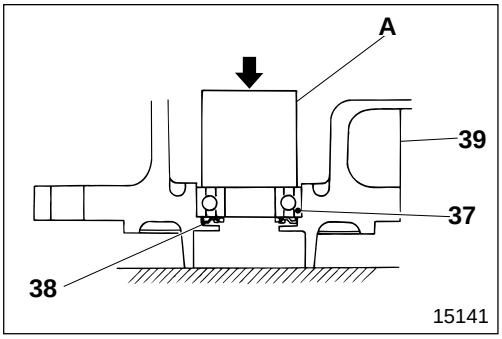
Perform the following checks, and if any fault is found, replace the overrunning clutch **33**.

- Make sure that shaft **A** turns smoothly when turned in direction **B**.
- Make sure that shaft **A** locks when turned in direction **C**.



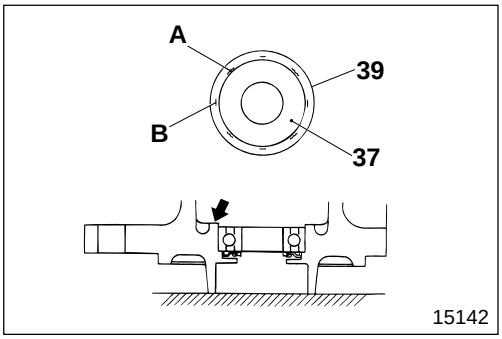
36 Installation of lever

Install lever **36** onto overrunning clutch **33** in the direction as shown.



37 Installation of front bearing

- Install oil seal **38** before press-fitting front bearing **37**.
- Press-fit front bearing **37** into front bracket **39** using pipe-shaped tool **A**.



- Re-caulk the side of front bracket **39**.

◆ Service procedure

● Inspection after assembly

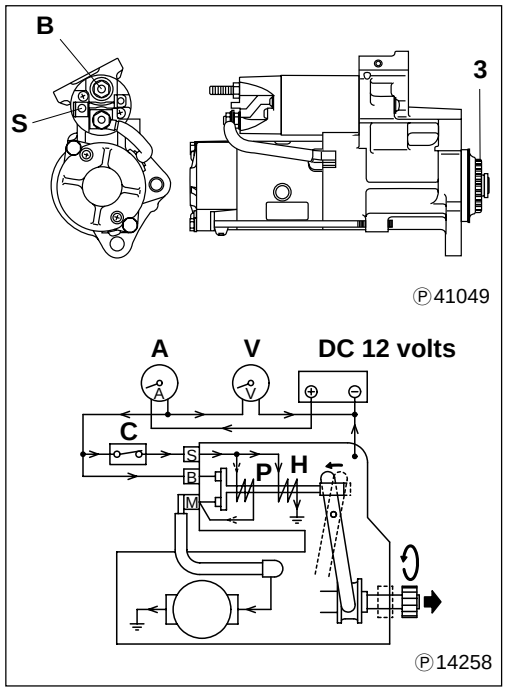
Inspection after assembling the starter should be carried out with current fed to the starter.

WARNING⚠

- **Do not touch pinion 3 because it jumps out and turns when current is fed to the starter.**
- **Take care not to burn your hand, magnetic switch assembly 5 might be hot during inspection.**

CAUTION⚠

- **The current feeding time to the starter should be within 10 seconds at pull-in coil P side and within 30 seconds at holding coil H side. If the current feeding time exceeds these limits the coil might burn due to overheating.**
- **The current, when fed to the starter, is over 100 amperes. When inspecting, use thick cable, such as a booster cable, and make secure connections.**



(1) Performance test

- Connect the starter as shown.
  A : Ammeter
  B : Terminal B of starter
  C : Switch
  S : Terminal S of starter
  V : Voltmeter
- Set the voltage to 11 volts DC.

CAUTION⚠

Up to 12 volts can be loaded.

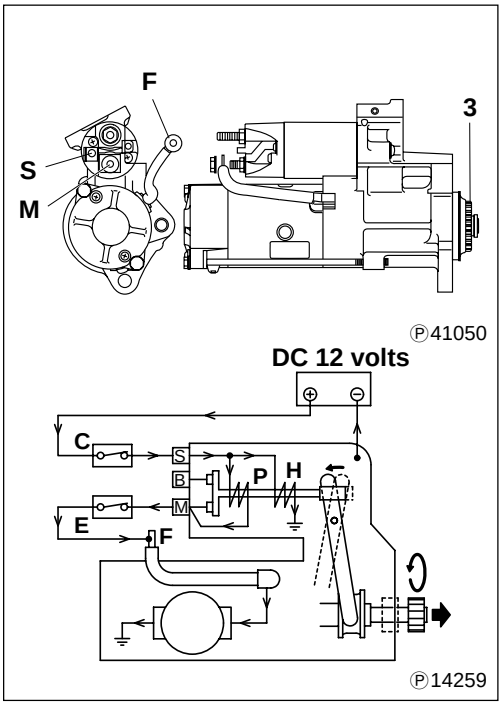
- The following work should be done with current fed to the starter. You must complete measurement of the current and the number of revolutions within 30 seconds.
  - Turn switch **C** ON and feed current to the starter. In this state, pinion **3** jumps out and rotates.

CAUTION⚠

When switch C is turned ON, current is fed both to pull-in coil P and holding coil H. When a large amount of current is fed into terminal M from DC 12 volts, via terminal B of the starter, the current stops flowing into the pull-in coil but continues to flow into the holding coil.

To avoid burning the holding coil, be sure to carry out the performance test within 30 seconds.

  - Measure the current and the number of revolutions of the starter. Train a strobe light on pinion **3** to measure the revolutions.
  - Turn switch **C** OFF to stop current to the starter.
- If the measured value deviates from the standard value, disassemble the starter again and inspect it.



(2) Pinion gap

[Inspection]

- Connect the starter as shown.
  C : Switch
  E : Switch
  F : Cable
  M : Terminal M of starter

- The following work should be done with current fed to the starter. You must complete measurement of the pinion gap within 30 seconds.
  - Turn switches **C** and **E** ON and feed current to the starter. In this state, pinion **3** jumps out and rotates.

  - Within 5 seconds of pinion **3** rotating, turn switch **E** OFF to stop rotation of the pinion.

CAUTION⚠

When switches C and E are turned ON, current is fed both to pull-in coil P and holding coil H. The circuit is wired in such a way that the voltage is not applied to terminal B of the starter, so the current continues to flow into the pull-in coil while pinion 3 rotates.
To avoid burning the pull-in coil, be sure to turn switch E OFF within 5 seconds of the pinion rotating.

  - Hold the end of overrunning clutch **33** with fingers, and pull it. Measure the distance **G** (pinion gap) in the shaft direction that the overrunning clutch moves when it is lightly pushed back by hand.
  - Turn switch **C** OFF to stop current to the starter.
- If the measured value deviates from the standard value, replace lever **36**.

CAUTION⚠

- **The current feeding time to the starter should be within 10 seconds at pull-in coil P side and within 30 seconds at holding coil H side. If the current feeding time exceeds these limits, the coil might burn due to overheating.**
- **Before making pinion 3 jump out, be sure to feed current to the starter to obtain the correct state. If current is not fed to the starter and lever 36 is pulled to protrude the pinion, front bracket 39 or the lever might be damaged due to the shock produced on removal of stopper ring 1.**
- **The current, when fed to the starter, is over 100 amperes. When inspecting, use thick cable, such as a booster cable, and make secure connections.**

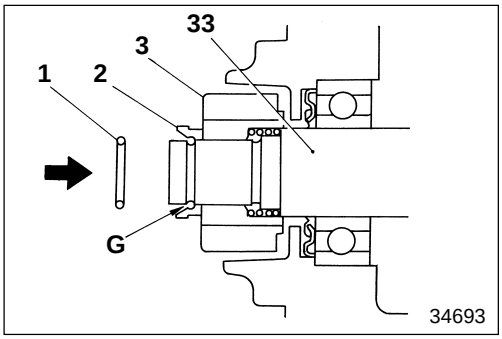
- Remove stopper ring **1** and pinion **3**.
- Turn switch **A** OFF to stop current to the starter.

NOTE

When the current to the starter is stopped, stopper ring 1 might fall back into ring groove F of pinion stopper 2 because pinion 3 is pushed inside.

If this occurs, feed current to the starter again and carry out the work.



[Installation]

When installing pinion **3**, it is not necessary to feed current to the starter.

- Install pinion stopper **2** and pinion **3** onto overrunning clutch **33** in the direction as shown.
- Fit stopper ring **1** into ring groove **G** of overrunning clutch **33**.

◆ Service procedure

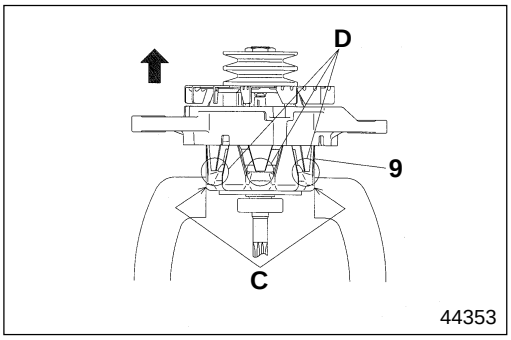
3 **Rotor and front bracket assembly**

[Removal]

- Insert screwdriver **A** between front bracket **12** and stator assembly **17**.
- Use the screwdriver **A** to pry rotor and front bracket assembly **3** away from stator and rear bracket assembly **13**.

CAUTION

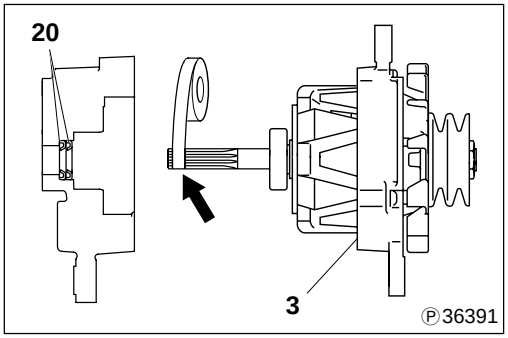
Be careful not to insert the screwdriver A too deep or it will damage coil B of stator assembly 17 and might cause a short-circuit.



[Disassembly]

CAUTION

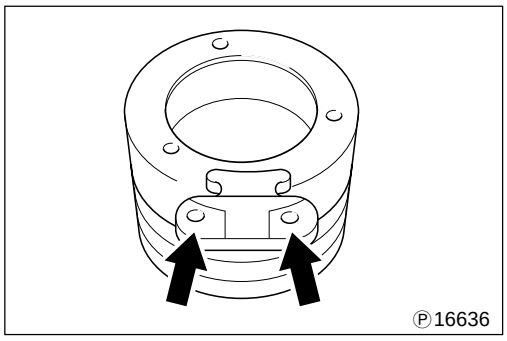
Make sure, when you hold rotor assembly 9 in a vise, to grip root C of the core claws. Gripping claws D can damage them.



[Installation]

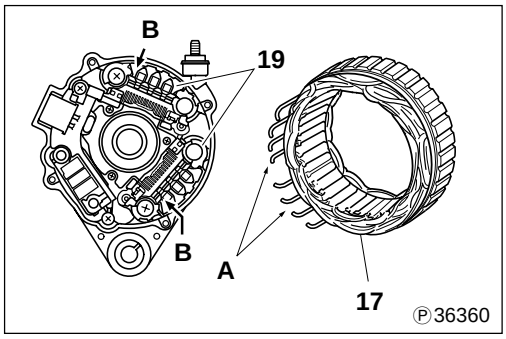
CAUTION⚠

To prevent damaging oil seal 20 during assembly, cover spline area E of the shaft of rotor and front bracket assembly 3 with tape.



[Inspection]

- Measure the resistance between the terminals of field coil **16**.
- If the measured value deviates from the standard value, replace field coil **16**.



17 Stator assembly

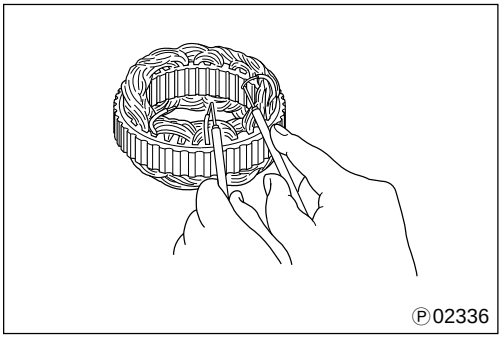
[Removal and installation]

- Disconnect lead **A** of stator assembly **17** from rectifier **19**. The lead is soldered to diode **B** of the rectifier at 8 places. (Each of the 2 rectifiers has 4 soldered sections.)

CAUTION⚠

Unsolder within as short a time as possible (within 5 seconds), or diode can be easily damaged by heat.

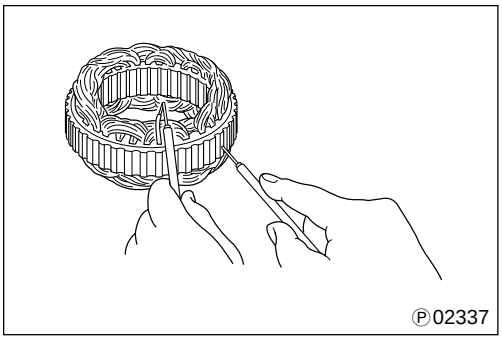
- To install, follow the removal sequence in reverse.



[Inspection]

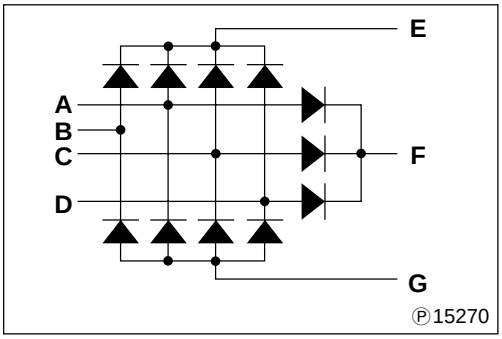
(1) Continuity between each lead wire

- Check that there is continuity between each stator lead.
- If there is no continuity, the lead is broken. Replace stator assembly **17**.



(2) Continuity between each lead wires and the core

- Check that there is no continuity between lead wires and the core.
- If there is continuity, the lead wires is short-circuited. Replace the stator assembly **17**.

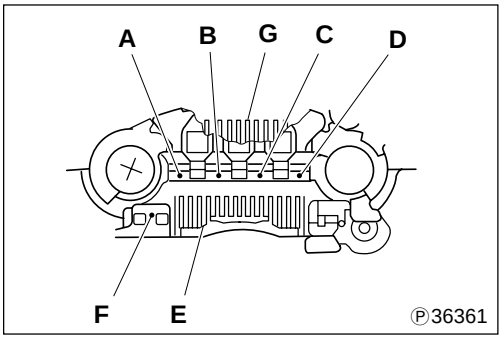


19 Inspection of rectifier

- Check the function of diodes within rectifier **19** properly. If any fault is found, replace the rectifier.

  If resistance is infinite in both cases, the diode is open.
  If resistance is close to 0Ω in both cases, the diode is shorted

  A, **B**, **C**, **D** : Lead connecting area of stator coil
  E, **G** : Heat sink area
  F : Regulator connecting area



- Inspection should be repeated with the positive probe and the negative probe of the tester changed over.

CAUTION ⚠

When inspecting using a tester, the current flowing through rectifier 19 is smaller than usual. Therefore, an incorrect resistance value might be indicated on the tester.
Also, incorrect indication become larger as the range of the tester gets smaller. Set the tester to a largest possible scale.

CAUTION

If screw 13 are removed first, the weight of field coil 14 may be placed on the joining portion with regulator 16 which is fixed with screw 12, causing break of the joining portion. To avoid this, remove screw 12 first.

- Remove screw **13** (3 places).

CAUTION

If screw 13 are removed, field coil 14 falls under its own weight. Keep the field coil supported by your hand.

- Remove field coil **14**.

CAUTION

Do not take out field coil 14 forcibly. Otherwise the joining portion with regulator 16 may be caught by the stator coil.

7 Inspection of alternator

(1) Alternator performance check (bench test)

- Connect the alternator **7** as shown.

CAUTION⚠

Sufficiently thick wires should be used for wiring and each connection should be securely fastened.

- Increase load resistance **F** to the maximum (condition which the load current hardly flow).
- Turn switches **C** and **D** ON.
- Run alternator at 5000 rpm for 30 minutes by adjusting load resistance **F** so that electric current can conform to the current specified in the service standard.

  Alternator nominal current

12V-100A

- Measure the current at each specified revolution of alternator **7**.
- If the measured value deviates from the standard value, disassemble and check alternator **7**. 📖 P54-12-42

B : Alternator terminal B
C : Switch
E : Alternator terminal E
G : Alternator drive motor
L : Alternator terminal L
R : Alternator terminal R
V : Voltmeter

- Turn switches **C** ON.
- Run alternator **7** at low speeds.
- Increase the speed of alternator **7** to 5000 rpm and measure the voltage (adjustment voltage) at this speed. At the same time, make sure that the current is 5 amperes or less at 5000 rpm.
- If the measured value deviates from the standard value, do as follows:
  - If higher than the standard value: Replace the regulator.
  - If lower than the standard value: Inspect the alternator related parts before replacing the regulator.

Removal and installation : Gr 37

Inspection : **270**

Perform inspection by turning the starter switch ON and determining the power steering fluid level when BRAKE warning lamp within the meter cluster lights (buzzer sounds at the same time).

(1) Inspection procedure when the power steering fluid level is low

- Drain the power steering fluid gradually from power steering oil tank **2**.
- Inspect to make sure that, when BRAKE warning lamp is lit, height **A** from power steering fluid surface to the **"MIN"** level of power steering oil tank **2**, is within the standard value.

(2) When power steering fluid level is too high

- Supply power steering fluid gradually into power steering oil tank **2**.
- Inspect to make sure that, when BRAKE warning lamp is lit, height **B** from power steering fluid surface to the **"MAX"** level of power steering oil tank **2**, is within the standard value.

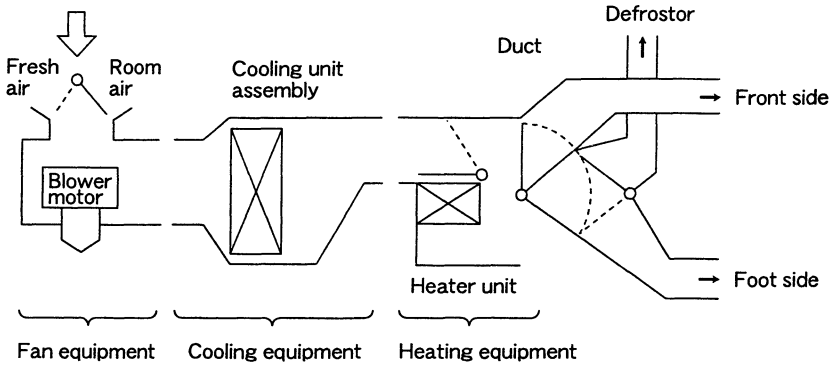
2. OUTLINES OF REFRIGERATION SYSTEM

2.1 Air system



Cooling operation

Fresh air is induced to the cooling unit assembly by a blower fan, where it is cooled down and dehydrated, charged at the front side outlet through a duct.

Heating operation

Fresh air is induced to the heater unit by a blower fan through the cooling unit assembly, where it is heated, then discharged at the foot side outlet through a duct.

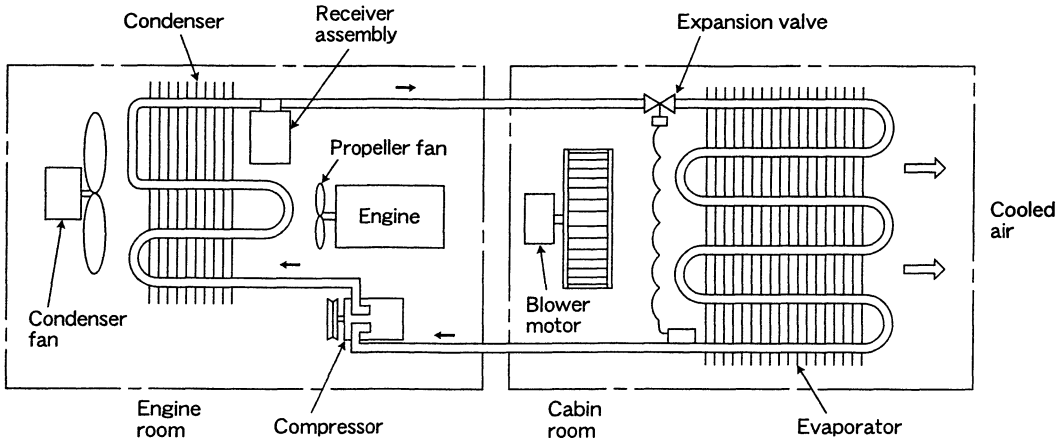
Dehumidifying operation

Fresh air is induced to the cooling by a blower fan, where it is cooled down and dehydrated, and succeedingly to the heater unit for warming, then discharged at the front side outlet through a duct.

Temperature control

Cooled air and warmed air are mixed for temperature control of the room inside.

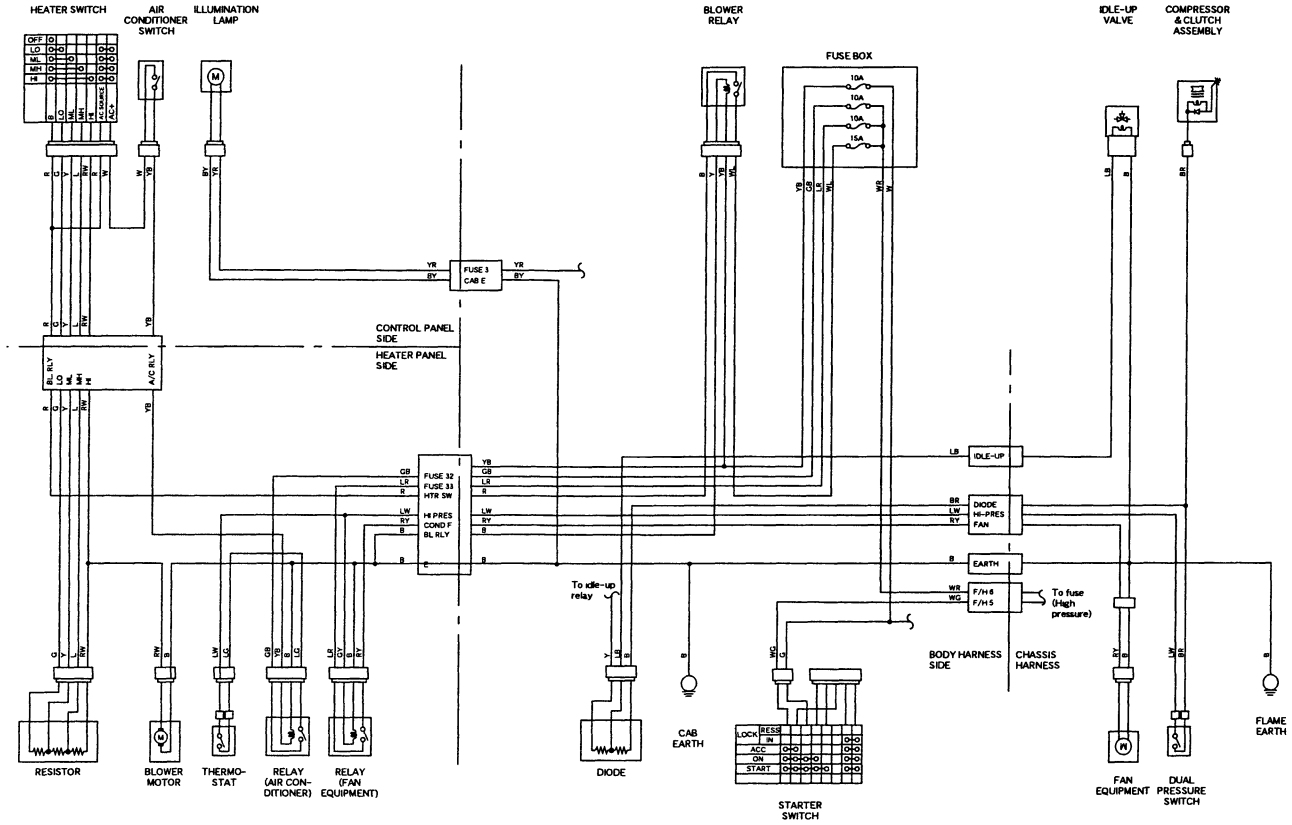
2.2 Refrigerating circuit



While the refrigerant, HFC-134a is cooling the air drawn into the evaporator, it evaporates and becomes a gas. This gas is compressed to high pressure and temperature in the compressor, and sent into the condenser, where it is cooled and becomes liquid.
This cooling in the condenser is carried out by the open air passing through the condenser sucked by radiator fan and vehicle motion of the vehicle.
The liquid refrigerant flows through the receiver assembly where water and dirt are removed, and then it enters the expansion valve. Here the liquid refrigerant is throttled and changed to a mixture of liquid and gas in low temperature and low pressure, and is sent to the evaporator.

In the evaporator, the refrigerant absorbs heat from the surroundings and becomes a gas. That is, because the evaporator it self is cooled at this time, the return air to the cooling unit assembly is cooled,
and the interior of the vehicle becomes cool. In this way the refrigerant flow makes a complete circuit.

2.3 Electrical system



The power source is supplied from the TRUCK battery. When the blower switch is put ON, the power relay becomes ON, and electricity is connected to the magnetic clutch of the compressor. The magnetic clutch switches ON or OFF by air conditioner switch, fin thermo, and low pressure switch as the controls for operation service, or safety protection.

The cabin room air temperature is set to a preset point by adjusting the temperature control lever, and the opening degree of the air mix damper.

(1) Control in panel

Do not run the air conditioner when it is child.

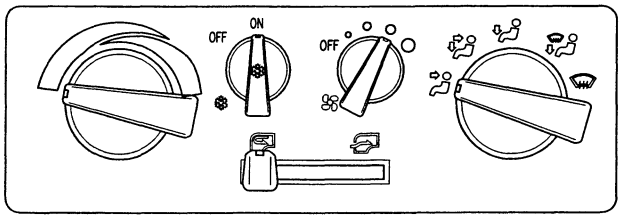
☐ Air conditioner switch
By select the air conditioner switch initially in cooling or drying operation, the compressor starts running.

☐ Fan switch
The air flow is selectable, out of the below four volume.

OFF	No air flow
◦	Gentle
o	Low
o	Medium
O	High

☐ Air outlet mode select switch
The air outlet is selected by positioning in cooling and heating operation.

- ----- The conditioned air is discharged at the center and both side outlets directed by the louvers as reguired.
- ----- The conditioned air is discharged at the center and both side and foot outlets directed by the louvers as reguired.
- ----- The conditioned air is discharged at the foot outlets directed by the louvers as reguired.
- ----- The conditioned air for dehumidifying is discharged at the foot outlets and to the front glass.
- ----- The conditioned air for dehumidifying is discharged to the front glass.



☐ Temperature control switch
The discharged air temperature is controllable by selecting the position of the control lever in cooling, heating or drying operation.

BLUE ZONE ------ For cool air flow
RED ZONE ------- For warm air flow

By turning the switch toward the BLUE and RED ZONE sides, the supply air temperature becomes more cooler and warmer respectively.

☐ Shift lever, air circulation
The recirculation air is selectable out of the below circulation modes.

- ----- Room circulation
- ----- Fresh air intake

(2) Operation control

Operation mode	Setting control lever	Air delivery	Remarks
COOL			Earlier cooling service, or conditioning at dusty, polluted air prevailing places : Shift lever : Air circulation
HEAT			Earlier cooling service, or conditioning at dusty, polluted air prevailing places : Shift lever : Air circulation Air outlet mode select switch
DEHUMIDIFY			Wetty conditioning in head cooled, and foot warmed : Shift lever : Air outlet Air outlet mode select switch

⑫ Shaft seal
⑬ Bearing
⑭ Needle bearing

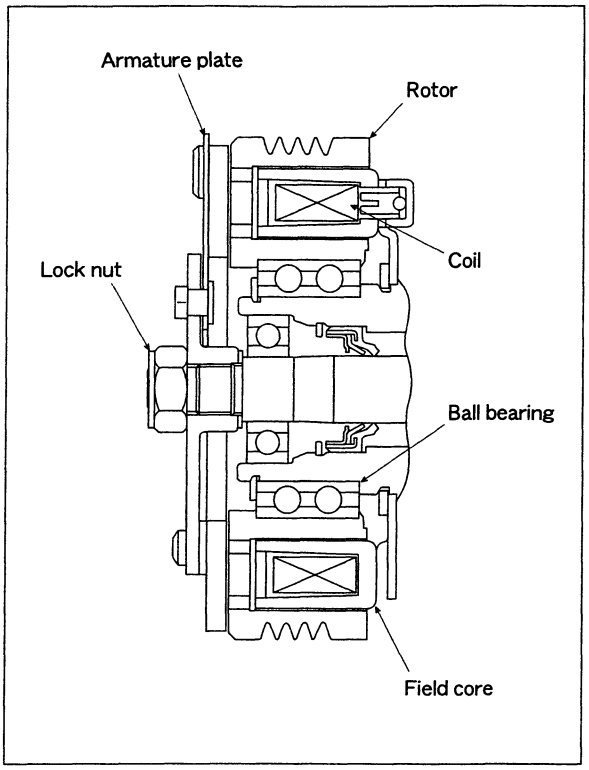
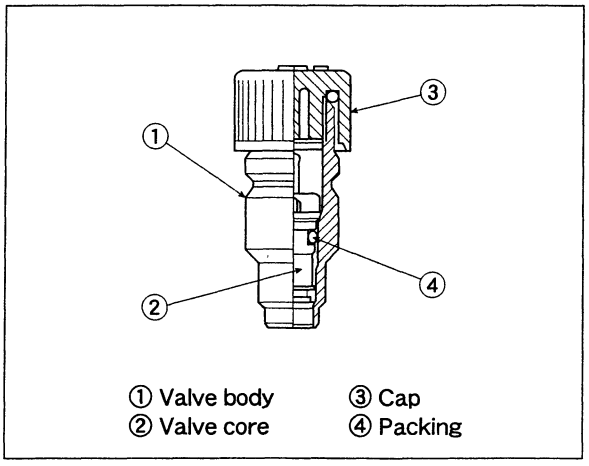
3.4.2 Magnetic clutch



The magnetic clutch is mounted on the compressor crankshaft to start and stop the compressor.
This means that the magnetic clutch is actuated to control the compressor operation electrically by the thermostat.

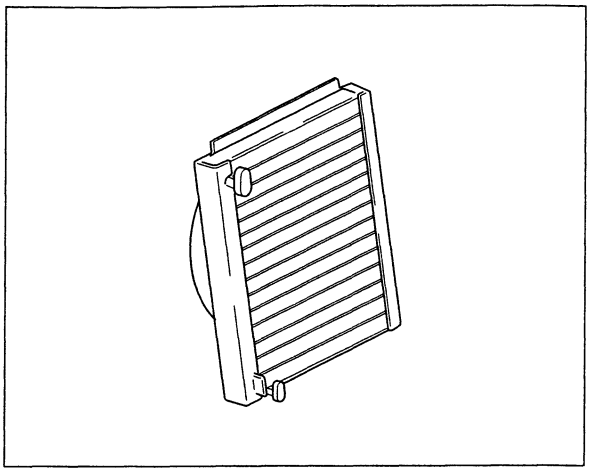
3.5 Check valve



① Valve body ③ Cap
② Valve core ④ Packing

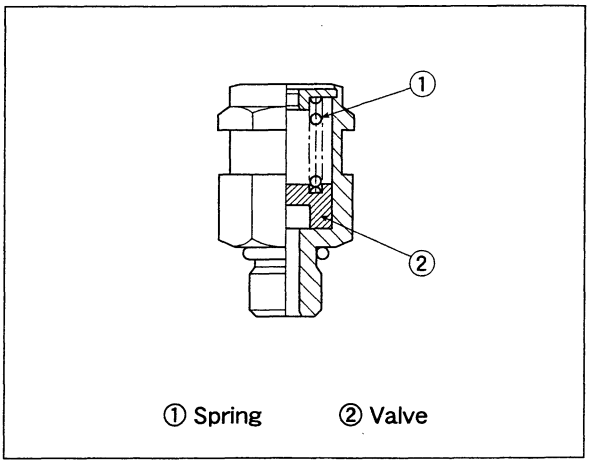
The suction hose and discharge hose are provided with check valve, and designed for gas evacuation and charging service. (shown above)
In the valves, a valve rubber tube, as in automobile tire tubes, is provided as shown in the figure.
Stackening the flare nut on the gauge manifold causes the passege to close automatically by the spring force, and tightening the flare nut causes the passege to open while pressing the compressed spring.

3.6 Side condenser assembly



The condenser is a means to liquefy the refrigerant gas. As the condenser is cooled by the air pulled in by the condenser fan, the refrigerant in the condenser is cooled into liquid. Therefore, when any obstacle prevents the air from flowing evenly to the condenser or the air flow is short circuited, the cooling effect is reduced, with a decrease in the performance of the condenser. When the vehicle is driven at a high speed, the air flow increases resulting in an increase of the cooling effect, and performance of the condenser.

3.7 Relief valve



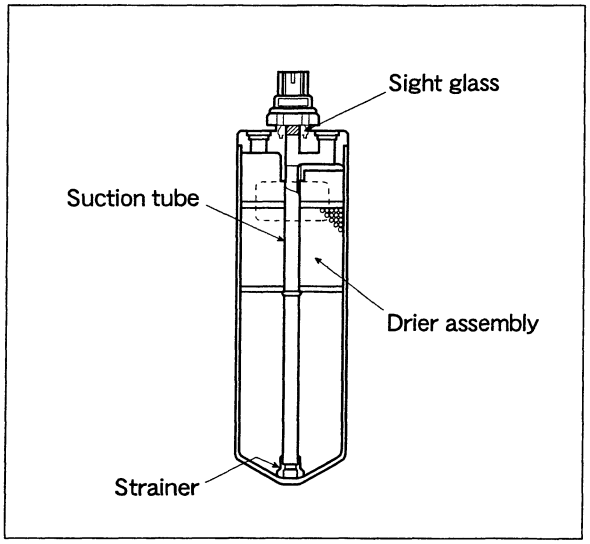
① Spring ② Valve

The relief valve is mounted to the compressor & clutch assembly. The relief valve is usually closed by spring. If pressure of refrigerant in air conditioner system is higher than spring pressure, refrigerant is discharged from relief valve. The pressure drop due to discharge refrigerant, and relief valve is closed again.

Unit : MPa

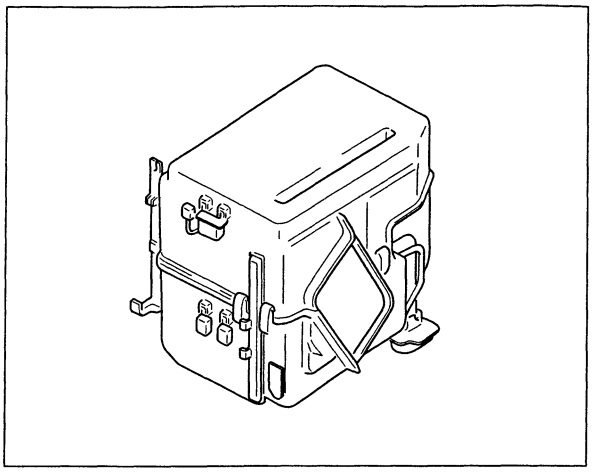
Open	3.50~4.10
Close	2.94

3.8 Receiver assembly



The receiver assembly is served as a refrigerant reservoir located between the condenser and expansion valve. The receiver assembly consists of a filter and a sight glass. The filter is used to remove dust , the drier is used to remove moisture from the refrigerant in the circuit, and the sight glass is used to check the refrigerant charge. Any moisture in the refrigerant may not only corrode metal surfaces in the refrigerant circuit, but also cause the throttle of the expansion valve to be frosted, resulting in the interruption of refrigerant circulation.
Therefore, the receiver assembly must be handled very carefully. When storing or installing it, care should be taken to protect it from the deterioration of drying performance due to exposure to the air.
The retardation of heat exchange, or any fire around the refrigerant circuit will cause excessive pressurization or heating of the refrigerant. Should such an accident occur, the refrigerant in the circuit must be expelled to the outside to prevent the above hazards.
The sight glass is a sort of peep window used to check the refrigerant flow in the refrigerant circuit.
The sight glass appears clear when the refrigerant flow is enough, and shows bubbles flowing when the refrigerant flow is short.

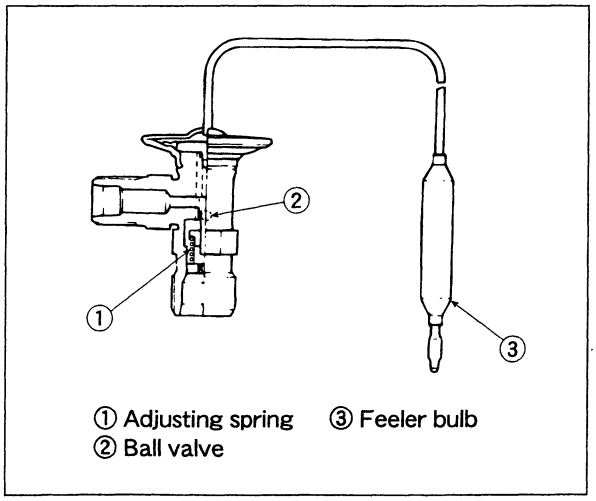
3.9 Cooling unit assembly



The evaporator core is a type of corrugated fin and tube. The tube is arranged in zigzag to achieve high effciency, and to make the core system compact.
A thicker reinforced plastic plate is used as the enclosure to inclease heat and shock resistance, and to protect the core from humidity. This case is a split type, and in a simple design to facilitate installation on the floor panel and the instrument panel frame of the vehicle.

3.10 Expansion valve

The expansion valve is mounted at the inlet of the cooling unit. The liquid refrigerant from the receiver is led to it through a narrow passage (for throttle action), where-in, the liquid refrigerant is condensed with pressure dropping and at the same time the flow rate is adjusted before the refrigerant is sent to the cooling unit.
The refrigeration load in the cooling unit is not constant, but usually fluctuates over a certain range. So the refrigerant flow should under go the control in design.
An automatic expansion valve performs this function automatically. The air condenser uses a thermal type automatic expansion valve.



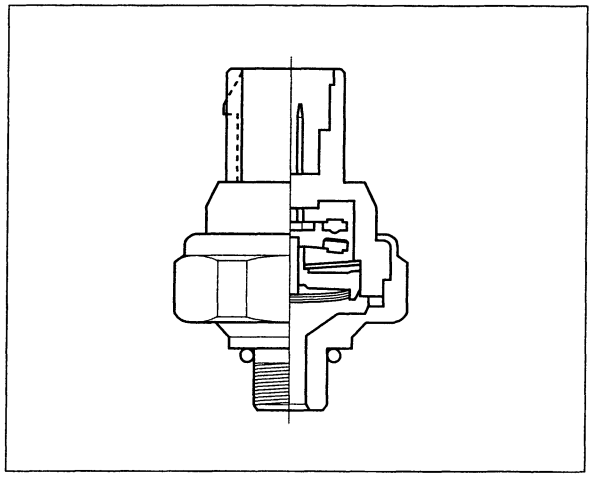
① Adjusting spring ③ Feeler bulb
② Ball valve

3.11 Dual pressure switch

The dual pressure switch, fixed to the receiver functions as a protector for stopping the compressor (OFF) at a preset value of pressure in the refrigerant circuit.

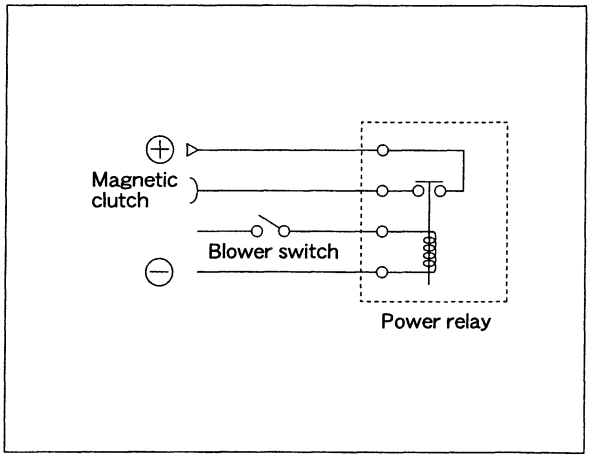
Unit : MPa

	LP side	HP side
OFF	0.2	2.94
ON	0.22	2.35



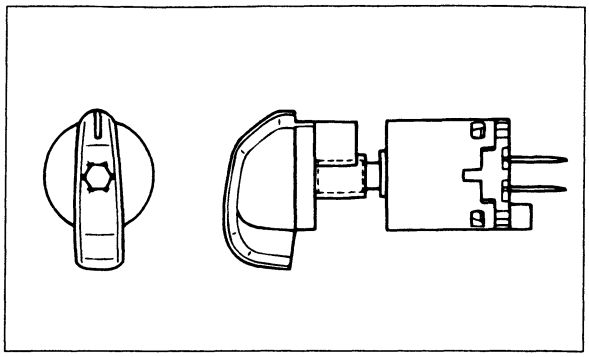
3.12 Power relay

The power relay is excited at a closed position of the micro switch and enables the magnetic clutch to be ready for engaging electically.



3.13 Air conditioner switch

The air conditioner switch function as an operation controller for starting or stopping the compressor in cooling and dehumidifying.
Set the it to the "ON" position, the magnetic clutch becomes engaged and the compressor starts.
Set the it to the "OFF" position, the magnetic clutch becomes disengaged and the compressor stops.

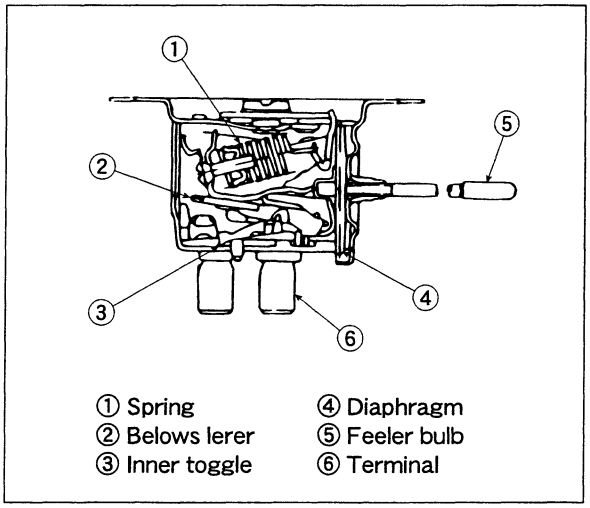


3.14 Thermostat

The thermostat is mounted on the evaporator case. It senses the temperature of evaporator fins, and controls the compressor operation for ON or OFF as specified below.

Unit : ℃

OFF	33
ON	38



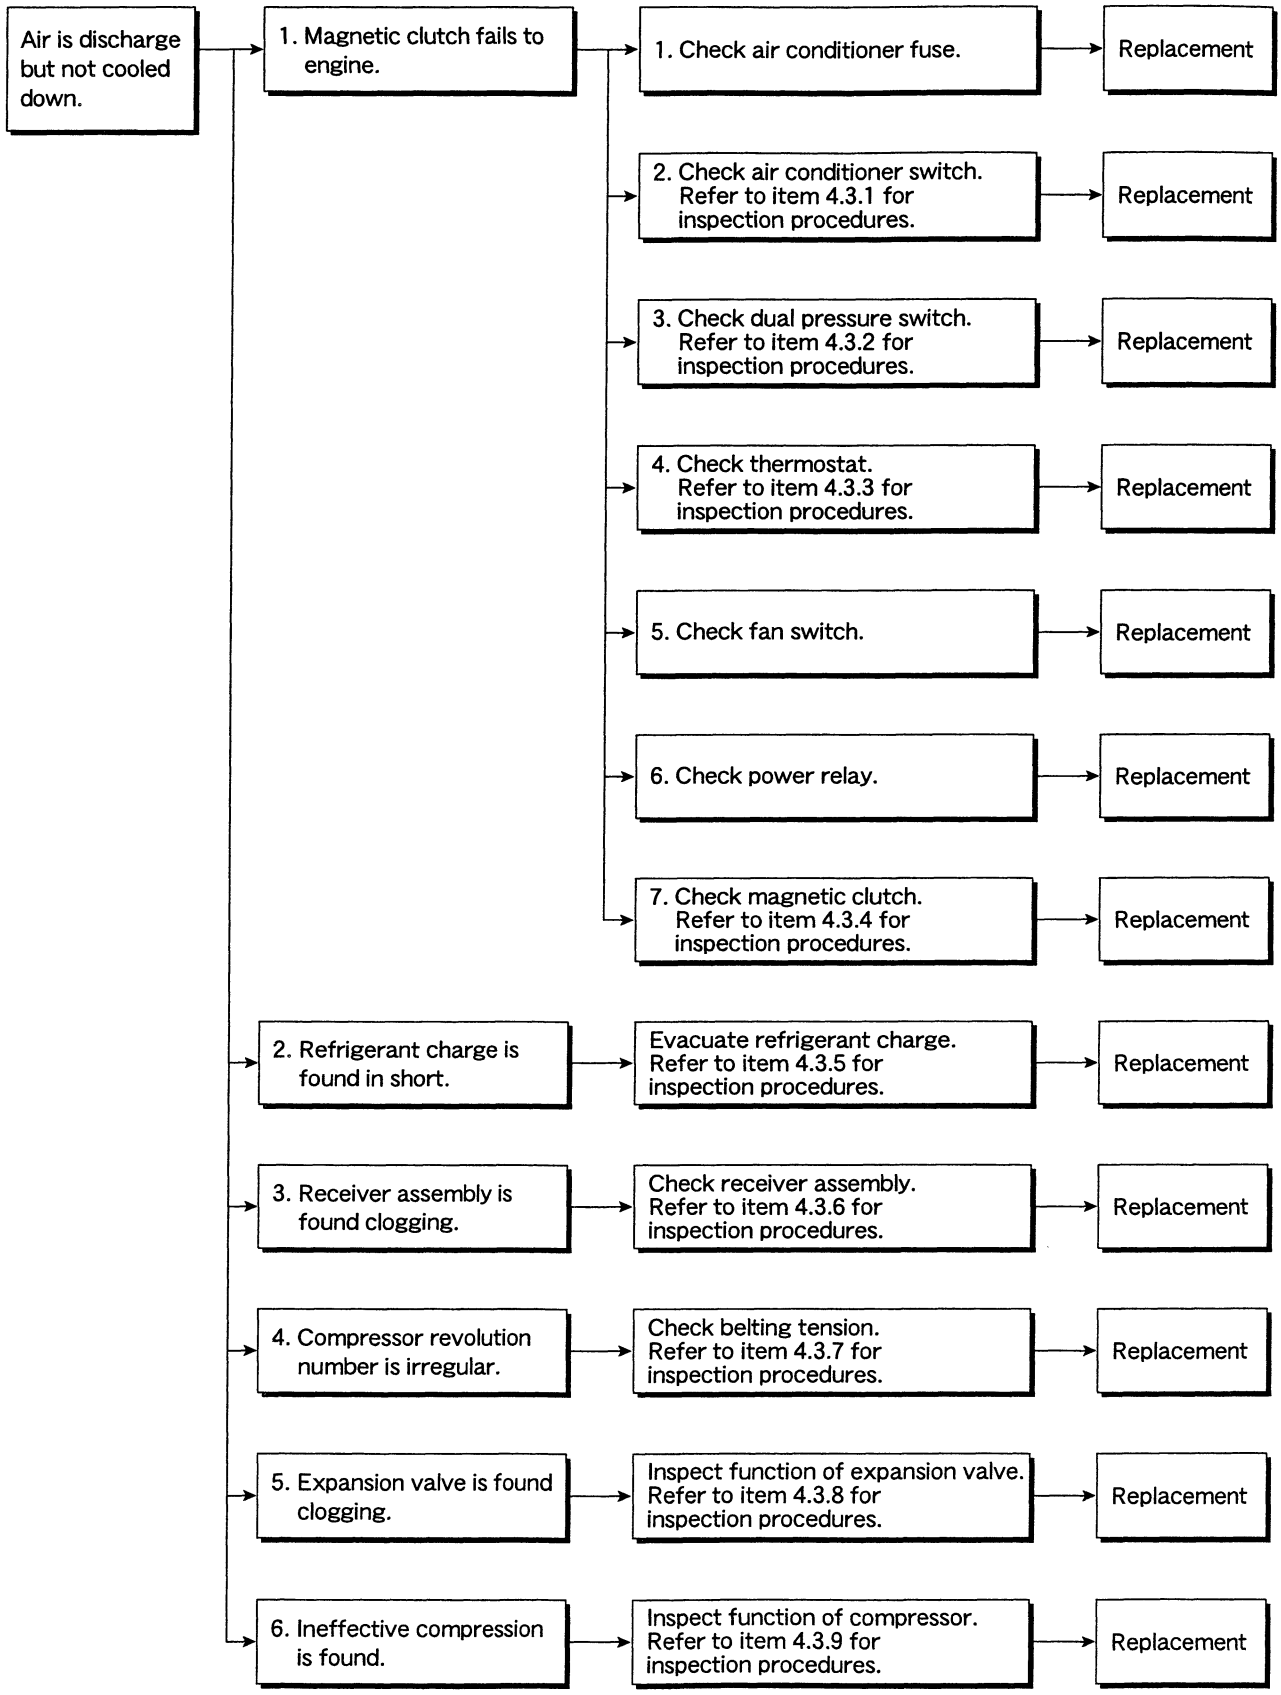
4 . TROUBLE SHOOTING

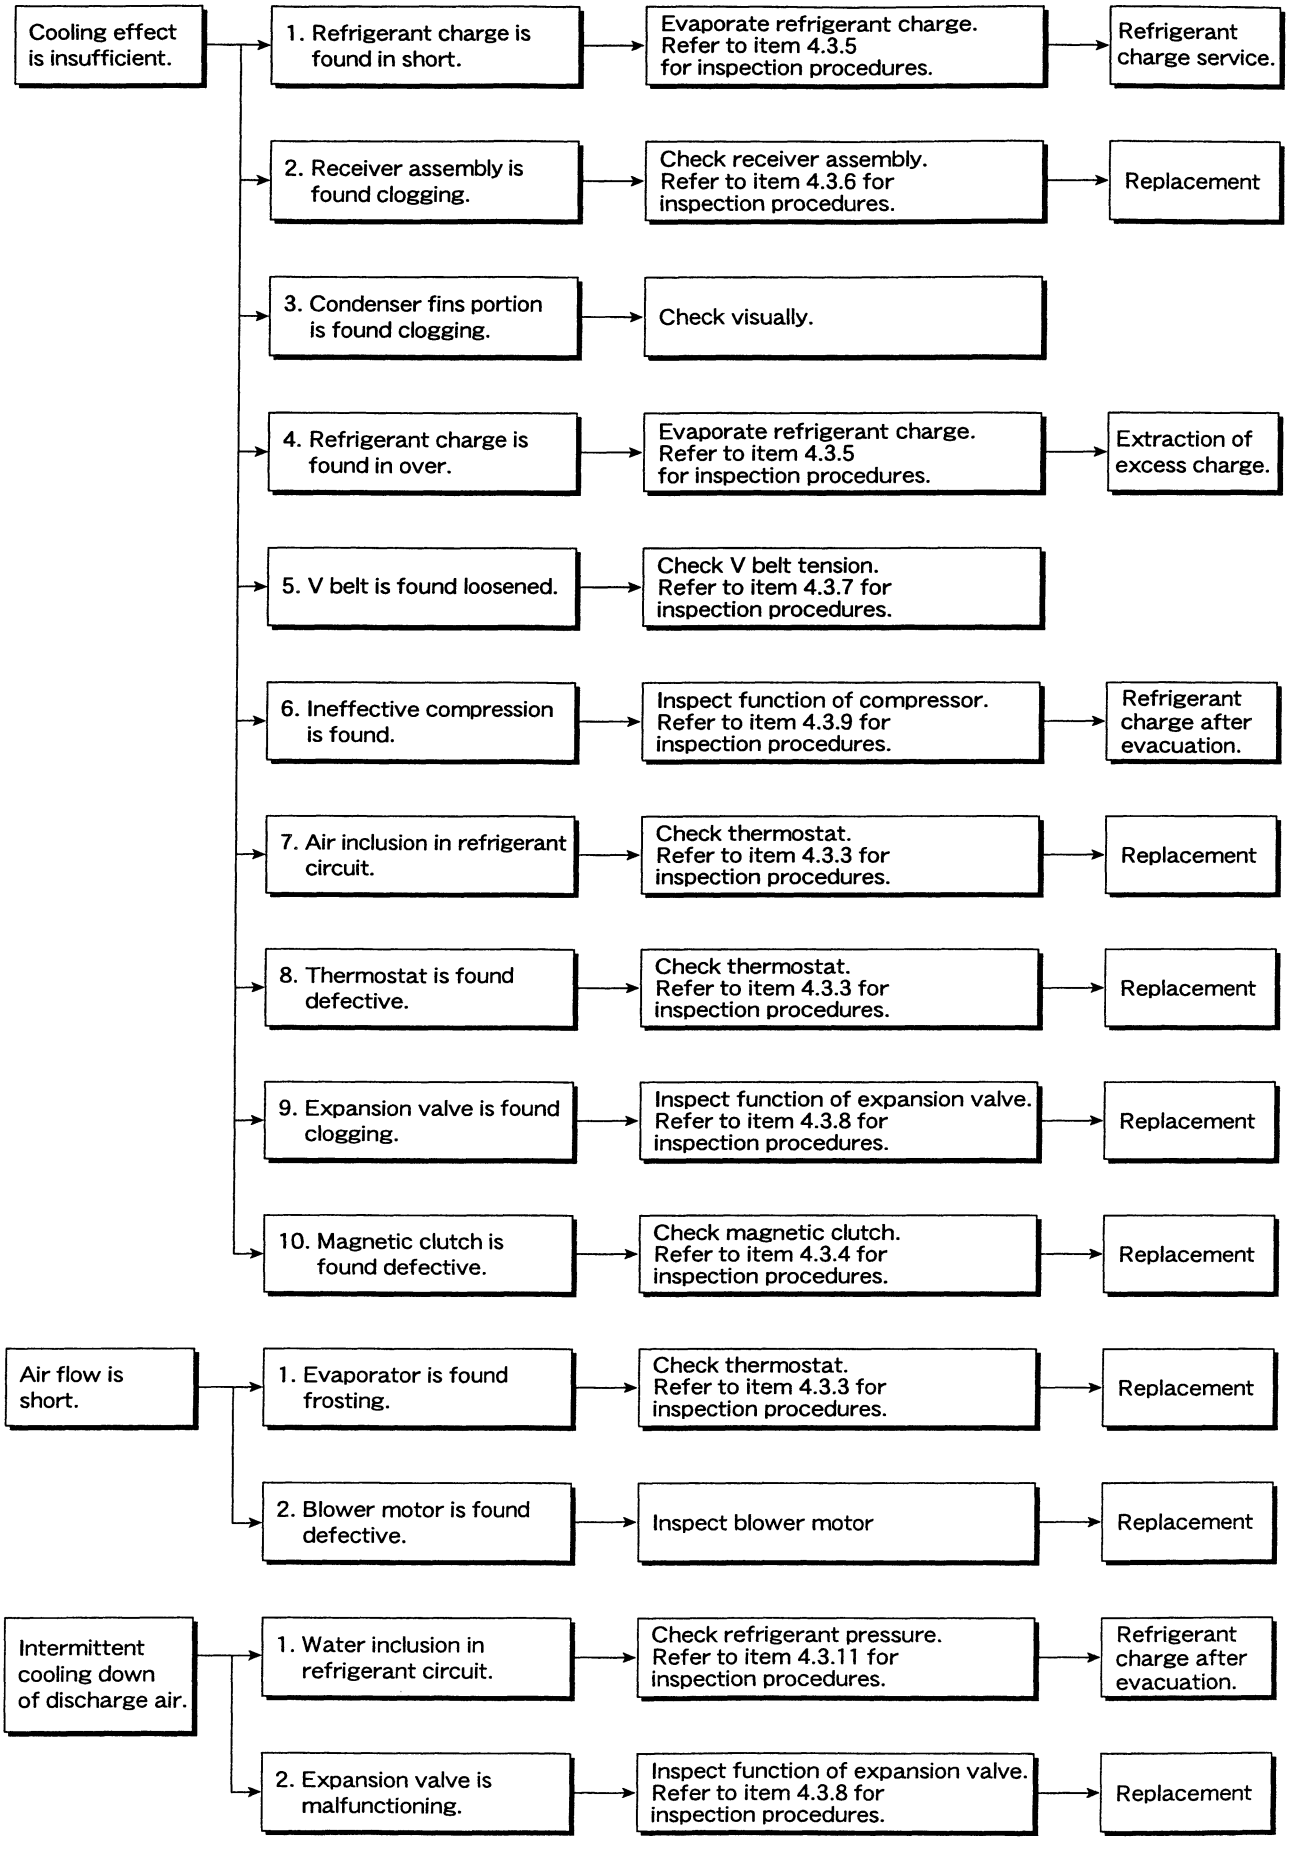
4.1 General precaution

(1) When handling refrigerant (HFC-134a), the following precautions must be observed.
   a. Allways wear eye protection and a pair of gloves which handling refrigerant.
   b. Be careful the liquid refrigerant dose not contact the skin.
   c. Keep the refrigerant container blow 40 degrees C.
   d. Do not handle the refrigerant in an enclosed area having an open flame. The refrigerant may produce a poisonous gas.
   e. When dumping the refrigerant from the system, release it slowly so as not to expell all the compressor oil.

(2) If liquid refrigerant strikes eye or skin.
   a. Do not rub eye or skin.
   b. Splash large quantities of cool water on the eye or skin.
   c. Rush to a physician or hospital for immediate professional treatment.

4.2 Trouble cause and remedy





Cooling effect is insufficient.
1. Refrigerant charge is found in short.
Evaporate refrigerant charge. Refer to item 4.3.5 for inspection procedures.
Refrigerant charge service.
2. Receiver assembly is found clogging.
Check receiver assembly. Refer to item 4.3.6 for inspection procedures.
Replacement
3. Condenser fins portion is found clogging.
Check visually.
4. Refrigerant charge is found in over.
Evaporate refrigerant charge. Refer to item 4.3.5 for inspection procedures.
Extraction of excess charge.
5. V belt is found loosened.
Check V belt tension. Refer to item 4.3.7 for inspection procedures.
6. Ineffective compression is found.
Inspect function of compressor. Refer to item 4.3.9 for inspection procedures.

4.3 Inspection procedure

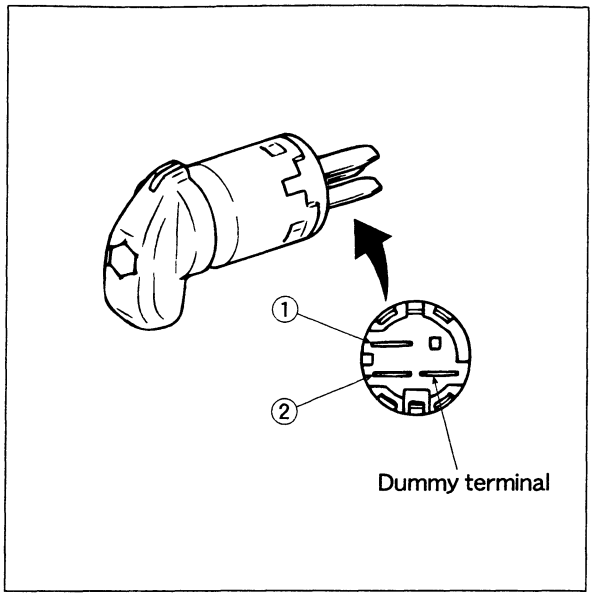
4.3.1 Air conditioner switch

(1) Unplug the air conditioner switch.
(2) Check the continuity between terminals of the air conditioner switch with a tester.

Continuity

Switch position	Terminal's number	Result, in normal
OFF	①-②	No
ON	①-②	Yes

Switch position \ Terminal's number	1	2
OFF	○	
ON	○	○

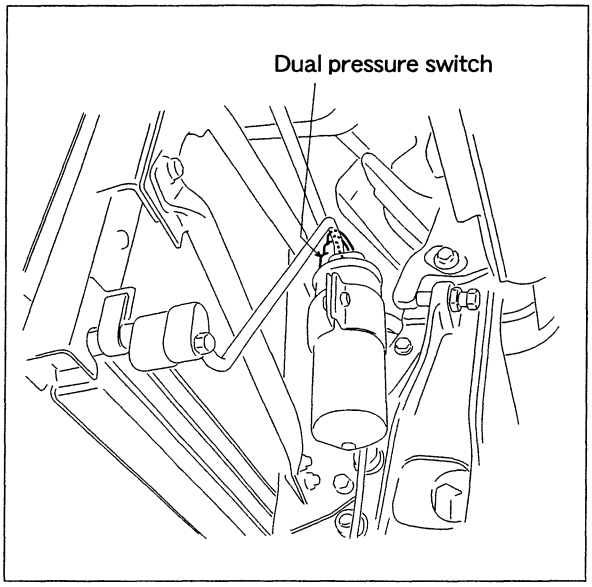


4.3.2 Dual pressure switch

The dual pressure switch is attached to the receiver assembly for controlling the operation of the air conditioner by checking the inside pressure of the receiver assembly.

Unit : MPa

	LP side	HP side
OFF	0.2	2.94
ON	0.22	2.35



(1) Unplug the connector at the receiver assembly.
(2) Check the continuity between terminals of the connector with a tester.
(3) When electric continuity is found, connect the connector to the high pressure switch.
(4) Attach the high pressure gauge and low pressure gauge.
(5) Operate the air conditioner.
(6) Cover the surface of the condenser by using a piece of paper.
(7) When the high pressure exceeds 2.94 MPa, if the magnetic clutch is turned off, the switch is normal.
(8) If the magnetic clutch is not turned off, replace pressure switch with new one.
(9) Check the accuracy of the preset as below.
  (a) Stop the air conditioner.
  (b) Purge the air conditioner of refrigerant slowly starting at over 0.22 MPa.
  (c) At reading the pressure 0.2 MPa, the switch opens.
  (d) Here, stop the purging, then turn it to charging.
  (e) At reading the pressure 0.22 MPa, the switch closes.

If the dual pressure switch does not meet specifications, replace the switch.

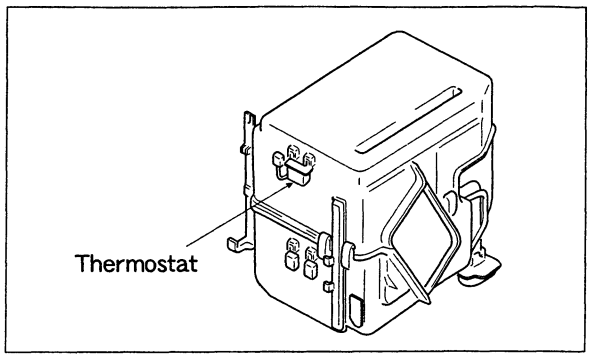
4.3.3 Thermostat

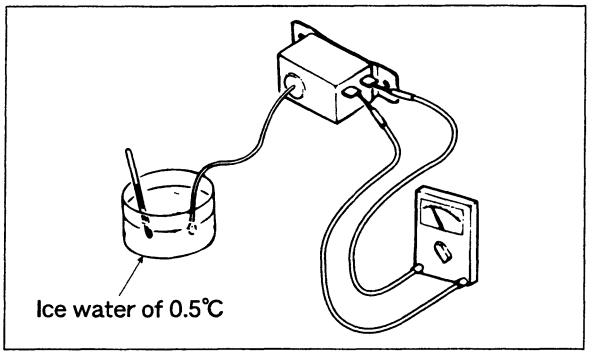
The thermostat is mounted on the evaporator case. It controls the operation of the air conditioner by sensing the temperature of the evaporator fins.

Unit : ℃

OFF	0.5
ON	3.5

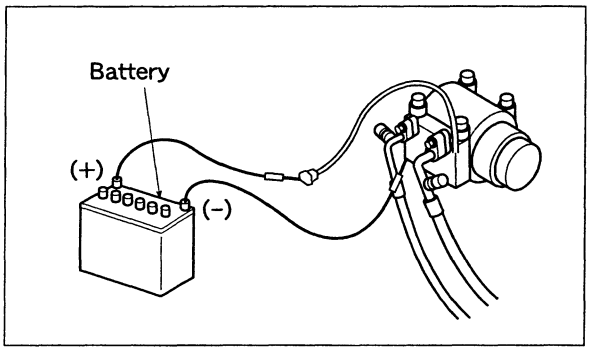
(1) Check the accuracy of the preset as below.
  (a) Soak the sensor of the thermostat in ice-water of below 0.5℃.
  (b) Check the continuity between the switch terminals.
  (c) Pull the senser out of the ice-water, and check the continuity at over 3.5℃ of the senser.





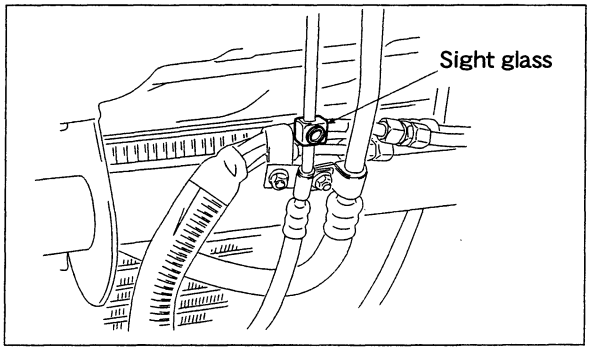
4.3.4 Magnetic clutch

(1) Disconnect the wiring to the magnetic clutch.
(2) Apply a positive side power voltage to the magnetic clutch through the wiring.
(3) In the case of regular functioning, the pulley and magnetic clutch are engaged with a clicking sound. The falling means any malfunction of the magnetic clutch.



4.3.5 Refrigerant charge

(1) Set the temperature control lever at the cool position.
(2) Open doors of the room.
(3) Set the blower switch at the ON position.
(4) Adjust the engine revolution at 1500min^{-1}.
(5) Operation the air conditioner switch for comp. ON.
(6) Watch the sight glass of the liquid hose at the inside of the engine room.
  (a) If judged insufficient refrigerant charging, repair the leaks, then charge it additionally.
  (b) If judged as over charging of refrigerant, extract an excess refrigerant.
(7) Diagnosis by pressure reading.
  (a) Short of refrigerant:
    Lower pressure for both LP and HP reading.
  (b) Express of refrigerant:
    Higher pressure for LP and HP reading.

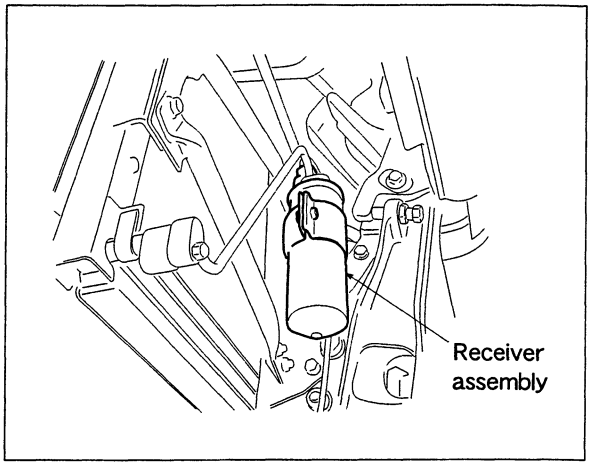


Sight glass		Remarks
Proper refrigerant level	Bubble	1. Bubble occasionally appears. 2. Bubble disappear if speed is a little increased.

Sight glass		Remarks
Insufficient refrigerant	Bubble	Considerable bubbles appear. If the system is extremely short of refrigerant, the sight glass appear white.
Excessive refrigerant		1. No bubbles appear. 2. Slight bubbles appear if speed is decreased.

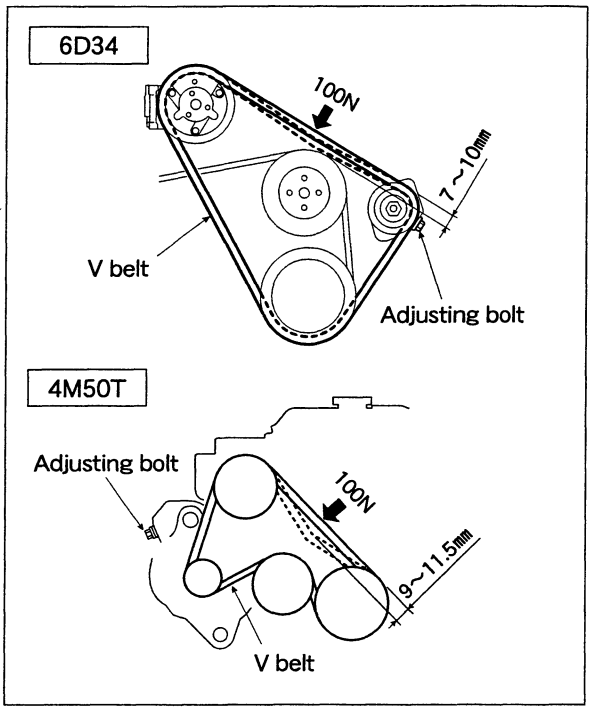
4.3.6 Receiver assembly

(1) While operating the air conditioner, touch the refrigerant piping with a hand at the inlet and outlet portions.
  (a) Sensed temperature difference:
    It is possible that clogging is happening at the inside, liquid receiver assembly is to be replaced with a new one.



4.3.7 Belt tension

(1) Depress the V belt with a thumb at the ⬅ marked position, and adjust the stretching as below.
  Stretching degree : 6D34 / 7～10 ㎜
    4M50T / 9～11.5 ㎜
(2) Adjustment
  (a) Loosen the nut of the tension pulley.
  (b) Control the belting tension by the adjusting bolt.
  (c) After finishing, retighten the nut as before.

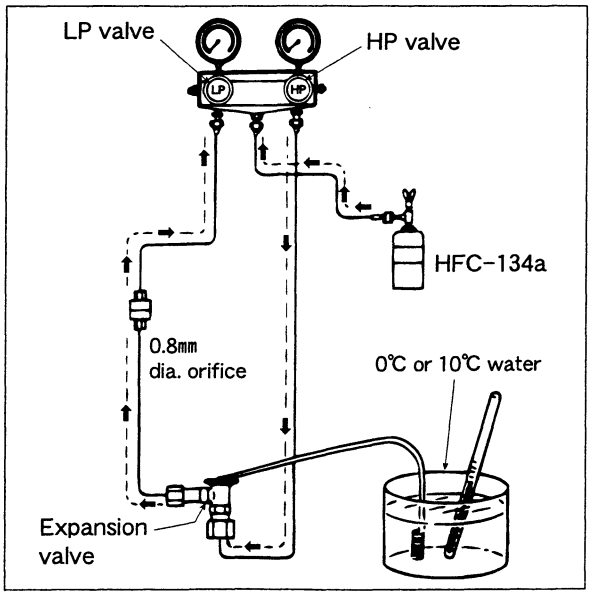


4.3.8 Expansion valve

⚠ CAUTION

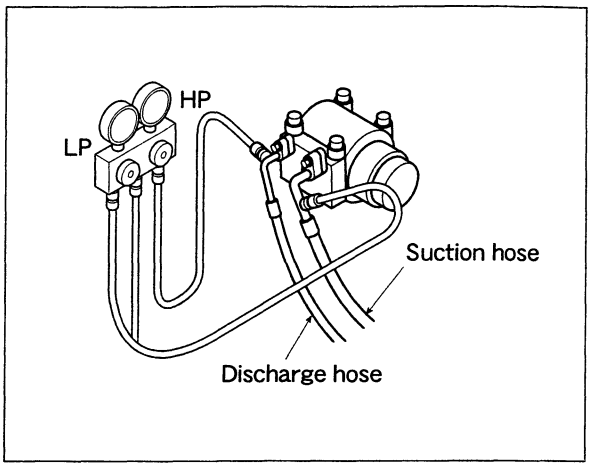
The test should be applied to only the case of the other components being free from troubles, and the expansion malfunctioning singly.

(1) Build up the test circuit with a gauge manifold.
(2) Soak the sensor bulb in ice water of 0℃, and of 10℃ respectively.
(3) Pressurize the HP side with dry nitrogen gas of 1.03MPa.
(4) Check the reading of the LP side pressure gauge for the standard range.
  At 0℃ ····0.127MPa
  At 10℃ ····0.23MPa



4.3.9 Pressure check

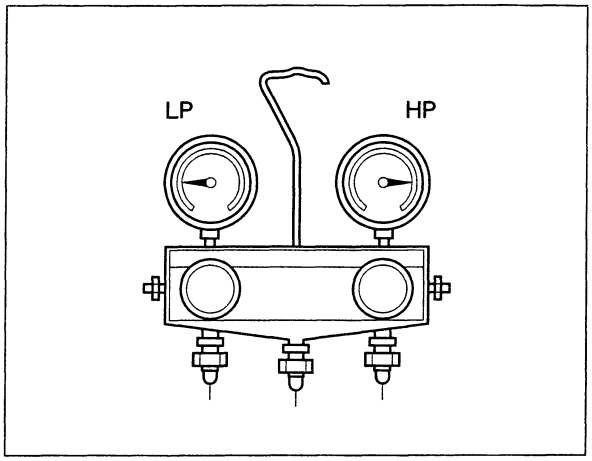
(1) Mount a low pressure gauge hose and a high pressure gauge hose on the check valve.
(2) Drive the air conditioner.
(3) Showing of higher LP side pressure and lower HP side pressure evidences ineffective compression.
Standard pressure
LP side pressure About 0.26MPa
HP side pressure About 1.42MPa



4.3.10 Air inclusion in ref.circuit

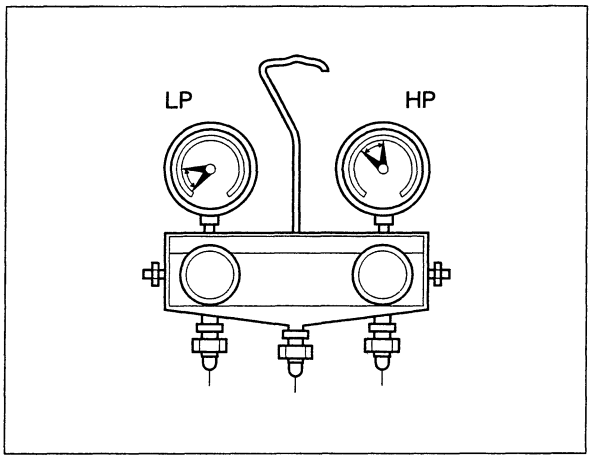
The abnormal reading of refrigerant circuit evidences afraid air inclusion.

A little higher LP side pressure. Noticeably higher HP side pressure.



4.3.11 Moisture inclusion in ref.circuit

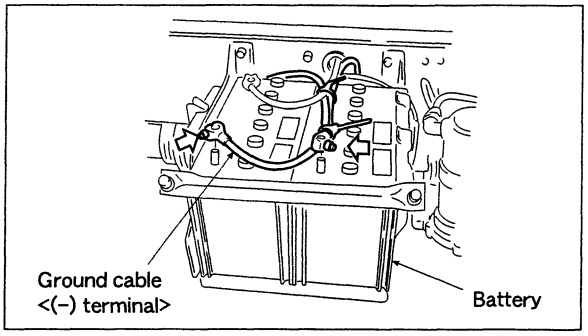
(1) During the operation, cooled air supply is interrupted periodically with a time interval.
This phenomenon evidences afraid water inclusion.
(2) Check the refrigerant pressure at a stop of the cooled air supply to make sure of the water inclusion.
LP side pressure ····Almost vacuum
HP side pressure ····Noticeably low



5. REMOVAL AND INSTALLATION

5.1 Precaution for removal and installation

(1) Disconnect the (-) ground cable from the battery, and place a cover on the battery.



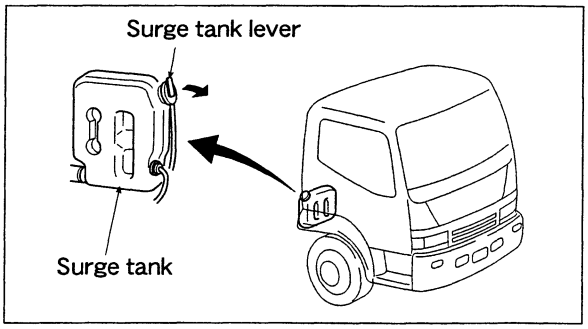
(2) Make certain all the openings are covered with caps in order to prevent entry of foreign substances such as dust and dirt.
(3) Never tamper with the brake and fuel systems, including the brake tubes and hoses.
(4) Avoid doing the work in a dusty place or outdoors in rainy weather. If tubes or functional parts are removed, put a cap in position immediately in order to prevent entry of dust and moisture.
(5) Connect the charging hose of the gauge manifold to the check valves (suction and discharge) of the suction hose and discharge hose, and recover the refrigerant by refrigerant recovery unit until its pressure is reduced to 0 kPa.
(Make sure that there is no internal pressure in the equipment.)
About discharging might result in the discharge of the refrigerant oil from the compressor.
(6) When coupling the flared tube, coat the flared portion with the compressor oil at the inner side.
(7) Make sure to use the wheel chocks.

5.2 Removal

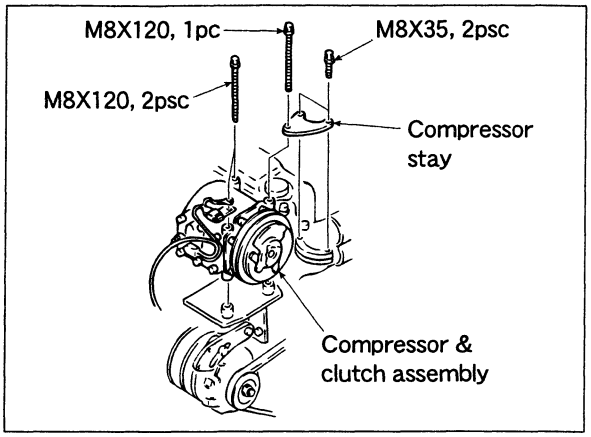
5.2.1 Inside engine room

(1) Compressor & clutch assembly

6D34

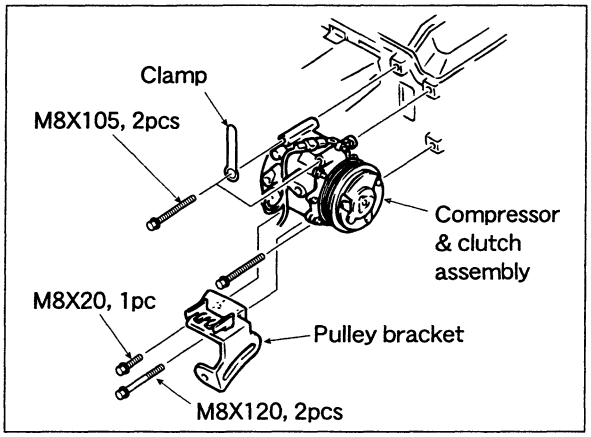


(a) Erect the pressure reducing lever of the radiator coolant surge tank cap to relieve the pressure from inside the radiator.
(b) Withdraw the wiring of magnetic clutch at the compressor.
(c) Remove the V belt by loosening fixture of the tension pulley.
(d) Take off the fixing bolts and anchor bolt : M8X35, 2pcs and M8X120, 1pc.
(e) Dismount the compressor stay.
(f) Take off the anchor bolts : M8X120, 2pcs.
(g) Dismount the compressor & clutch assembly.

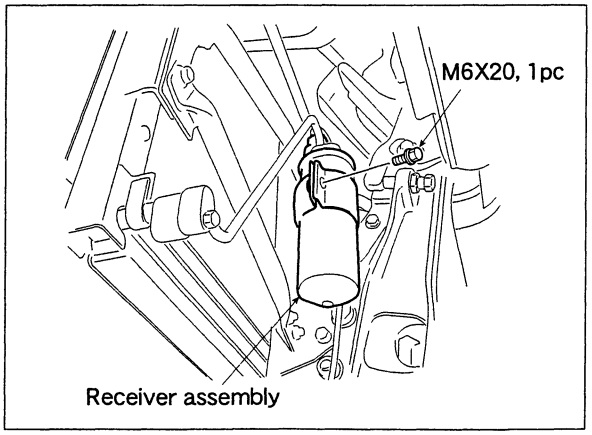


4M50T

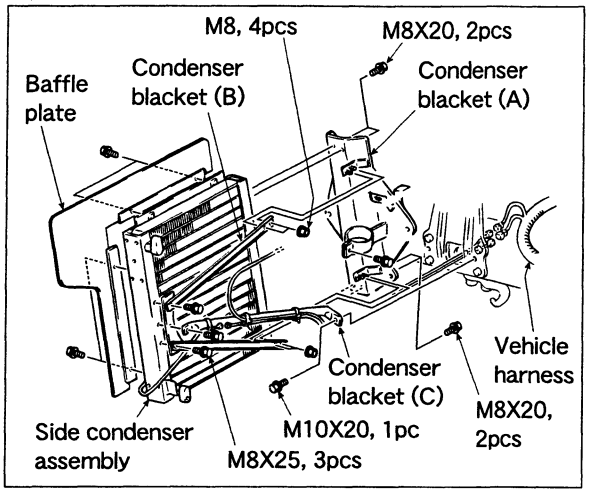
(a) Withdraw the wiring of the magnetic clutch at the connector.
(b) Remove the V belt by loosening fixature of the tension pulley
(c) Take off the fixing bolts : M8X105, 2pcs and M8X 120, 2pcs. (with clamp) and M8X20, 1pc.
(d) Dismount the compressor.



(2) Reciever assembly
(a) Unplug the dual pressure switch at the connector.
(b) Separete the interconnecting refrigerant pipe of the receiver assembly.
(c) Take off the fixing bolt : M6X20, 1pc.
(d) Dismount the receiver assembly.

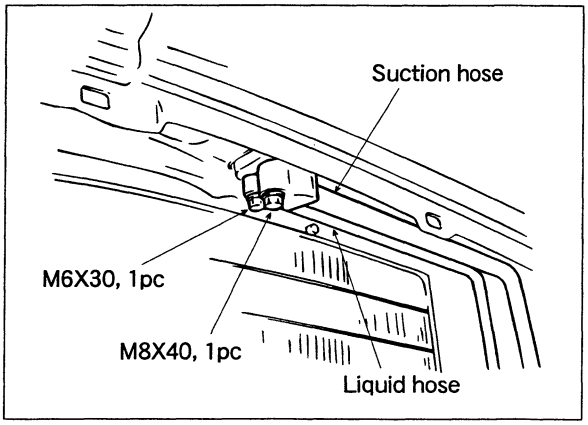


(3) Side condenser assembly
(a) Unplug the condenser fan harness at the vehicle side harness.
(b) Take off the fixing bolt : M8X25, 3pcs and M10X20, 1pc.
(c) Take off the fixing nut : M8, 4pcs.
(d) Dismount the condenser blacket (A), (B), (C).
(e) Take off the fixing bolt : M8X20, 4pcs.
(d) Dismount the side condenser assembly (and baffle plate).

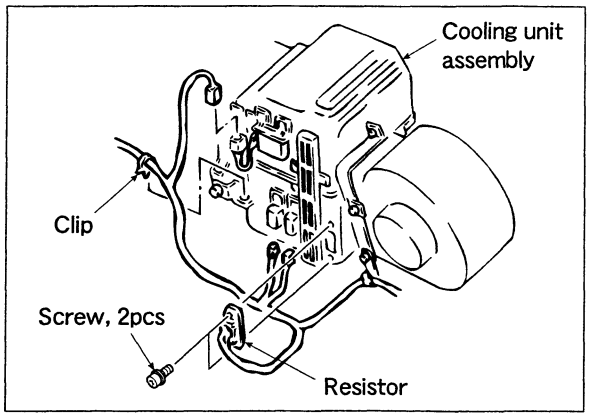


5.2 Cabin room

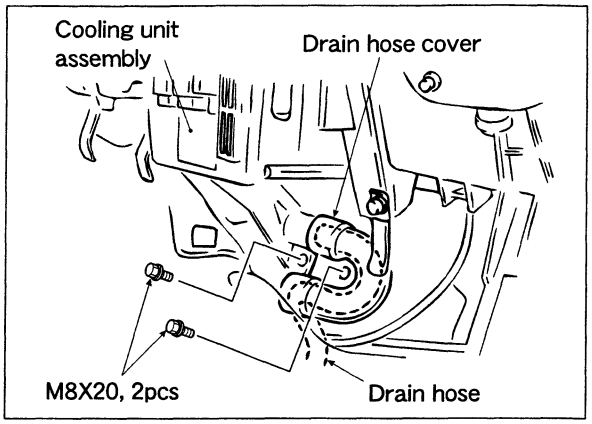
(1) Cooling unit assembly
(a) Separate the interconnecting refrigerant pipes of the cooling unit assembly.



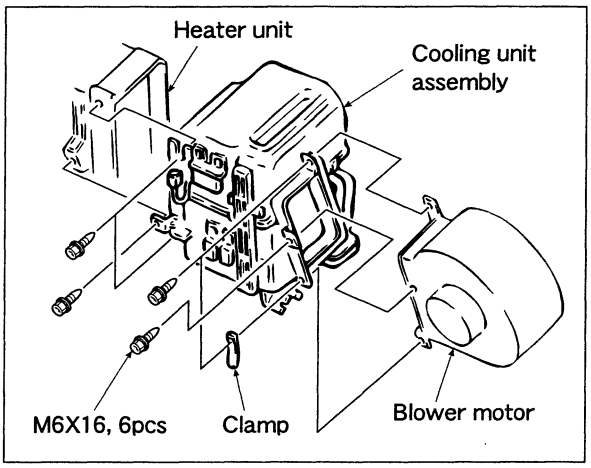
(b) Withdraw the wiring of the cooling unit assembly at the connectors.



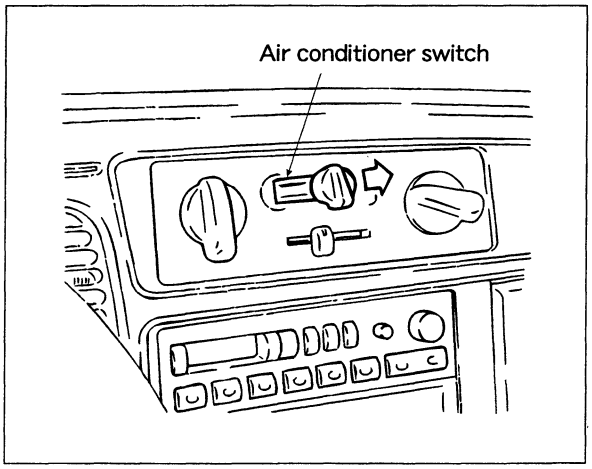
(c) Take off the fixing bolt : M8X20, 2pcs.
(d) Dismount the drain hose cover.
(e) Reconnect the drain hose from the cooling unit assembly.



(f) Take off the fixing screws : M6X16, 6pcs.
(g) Dismount the cooling unit assembly.



(2) Air conditioner switch
Pull out the air conditioner switch.



5.3 Installation

Installation is performed in the opposite sequence of removal.

NOTE

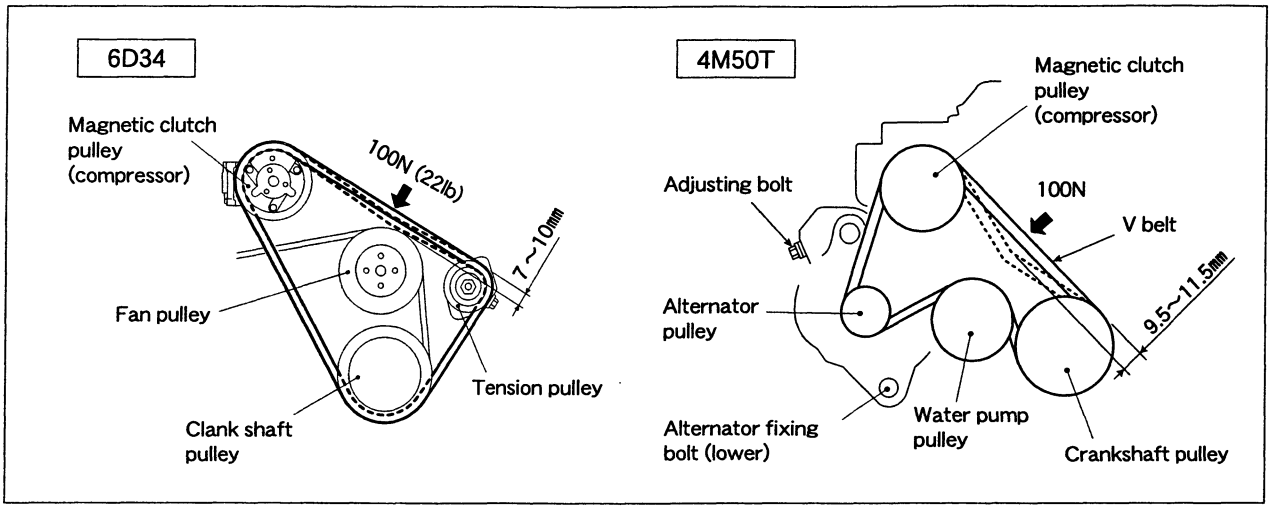
For the cases of spring washer seated, and thread or seating surface coated with oil, the value shall be reduced down to 85 percent of the data listed.

6. TREATMENT AFTER INSTALLATION

6.1 Check and adjustment

After installation, check the following points and confirm that everything is normal, then charge the gas, and do the performance and operation tests.

(1) Check if any abnormal vehicle performance, happens or not by installing the air conditioner.
(2) Check the operation of the magnetic clutch. (with the compressor disengaged)
(3) Check if any parts left unmounted or any tool left in the vehicle.
(4) Check to ensure that the temperature control lever operates properly.
(5) Check the tension of the belt.



6.2 Leak test

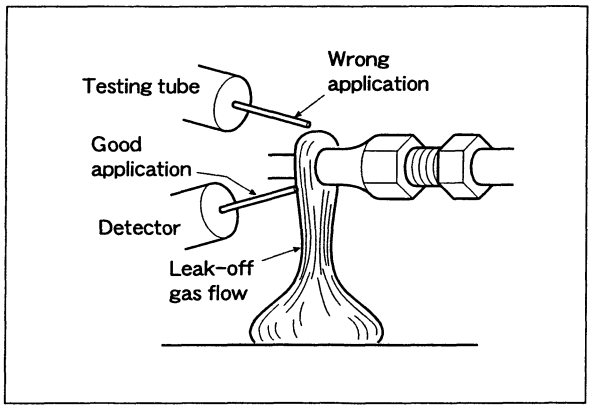
After all the piping works are completed, conduct an leak test by the following procedure to check any leaks at the flare coupling, etc. and then evacuate the system. If this leak test is omited and evacuation is immediately started, there is no way of detecting possible leak. If there are leaks, the specified vacuum cannot be attained. In order to save the service time be sure to conduct the leak test before evacuation.

6.2.1 Test point

(1) All pipe joint.
(2) Shaft seal and check valve on the compressor.

6.2.2 Test procedure

(1) For the gas leak test, the use of an electric gas leak detector is recommended. (HFC-134a SAE Approved)
(2) Perform the test at a place as in free from air flowing.
(3) The refrigerant is heavier than air. Leaks will concentrate at the bottom. Make certain that the testing tube is applied below the check point.



(4) The test should be performed patiently. Make certain that testing tube is moved slowly [approx. 10mm/sec].
(5) The high pressure side refrigerant circuit should be tested for gas leaks during operation. Those areas which are dangerous or hard to test during operation (including areas around the compressor and condenser) should be tested direct after shutdown.

(6) The low pressure side refrigerant circuit should be tested during shutdown after the gas pressure has balanced.
(7) The test should be performed on the basis of the following standards:

Gas leak test standards

test point / Instrument	Compressor shaft seal	Other parts
Electric gas leak detector	Pointer shall not swing more than 0.1mA at the low sensitivility.	Pointer shall not swing more than 0.1mA at the low sensitivility.
handle torch gas leak detector	Flame colour (moss green) shall not change.	

⚠ WARNING

- Smoking should be forbidden if a gas leak is detected.
- If a flame is applied to the refrigerant, toxic phosgene gas will be produced. Do not keep the detector in contact with a leaky point for a long time.

- Leak test procedure

1. Attach refrigerant supply and gauge set as shown with all valves closed. Open refrigerant supply valve on can.
2. Loosen the center charging hose fitting at the gauge manifold end to blow any air from the hose until it hisses for a few seconds, then refrigerant.
3. Open both gauge valves to partially charge the system and then close both valves.
4. The system can then be checked for leaks using an electronic leak detector.
5. If leaks are found that require the system to be opened (to repair or replace hoses, fittings, etc.), release any charge in the system.
6. After checking and repairing leaks, system must be evacuated.

6.3 System charging

GENERAL PRECAUTIONS

⚠ WARNING

When handling refrigerant (HFC-134a), the following precautions must be observed.

- Always wear eye protection and gloves while handling refrigerant.
- Be careful that liquid refrigerant does not contact the skin.
  If liquid refrigerant strikes eye or skin:
  - Do not rub on skin.
  - Splash large quantities of cool water on the eye or skin.
  - Flush eyes or skin with cool water for 5 minutes.
  - Rush to a physician or hospital for immediate professional treatment.
  - Do not attempt to treat it yourself.
- Keep the refrigerant (HFC-134a) container below 40℃.
- Do not handle the refrigerant in an enclosed area having an open flame; the refrigerant may produce a poisonous gas.
- Use approved recovery equipment to recover HFC-134a refrigerant before attempting service of this or any other HFC-134a system.
- Do not attempt to leak test an HFC-134a system with high pressure air or nitrogen. Mixing HFC-134a with a concentrated quantity of air may be combustible in the presence of ignition.

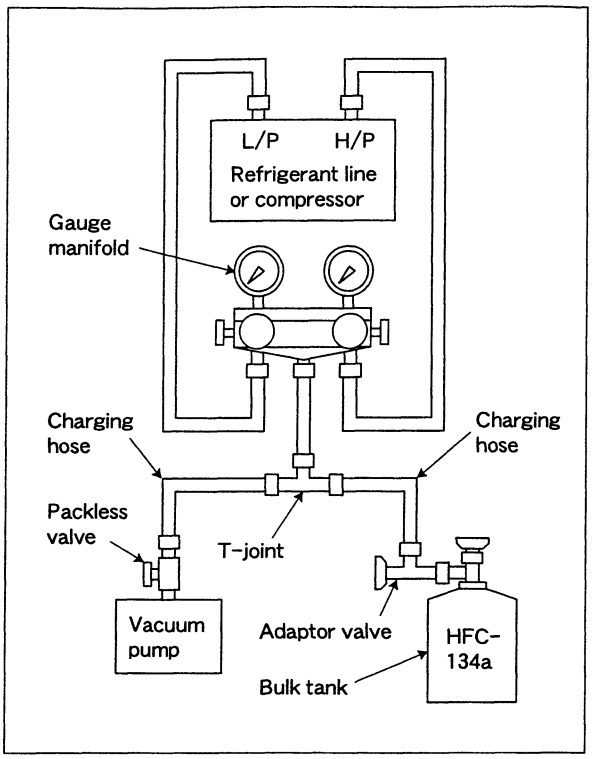
6.3.1 Evacuation

INSTALLATION OF CHARGE EQUIPMENT

(1) Connect the gauge manifold to the service valves.
(2) Connect the packless valve to the vacuum pump.
(3) With the charge valve handle turned back all the way, install the bulk tank.
(4) Connect each charge equipment as illustrated.

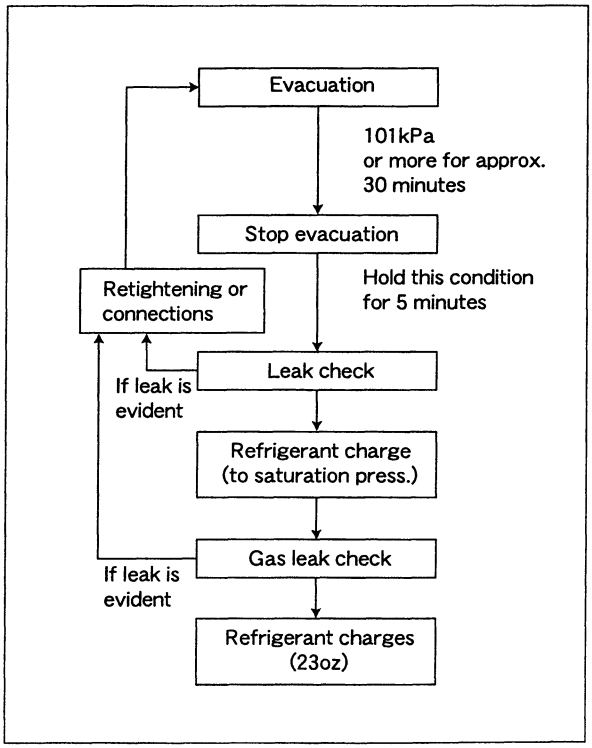
⚠ CAUTION

1. Do not connect the high and low pressure sides adversely. (Connect high pressure side to the condenser and low pressure side to the cooling unit.)
2. The indications "DIS" and "SUC" on the compressor indicate high and low pressure sides respectively.



6.3.2 Evacuate the system

The refrigerant system must have been evacuated using the previous procedure before charging. Charge using only HFC-134a refrigerant. HFC-134a is available in bulk tank. Follow the safety precautions for handling HFC-134a as listed in this section.
Follow the evacuation procedure below and at right.
This procedure assumes no HFC-134a refrigerant has been introduced into the system. If evacuating a charged system, it is necessary to recover the existing HFC-134a refrigerant before continuing with these instructions.
Refer to the recover equipment manufacture's instructions for proper refrigerant recovery.



CHARGING WITH BULK TANK

When using disposable cans of this type, follow carefully the tank manufactures instructions.

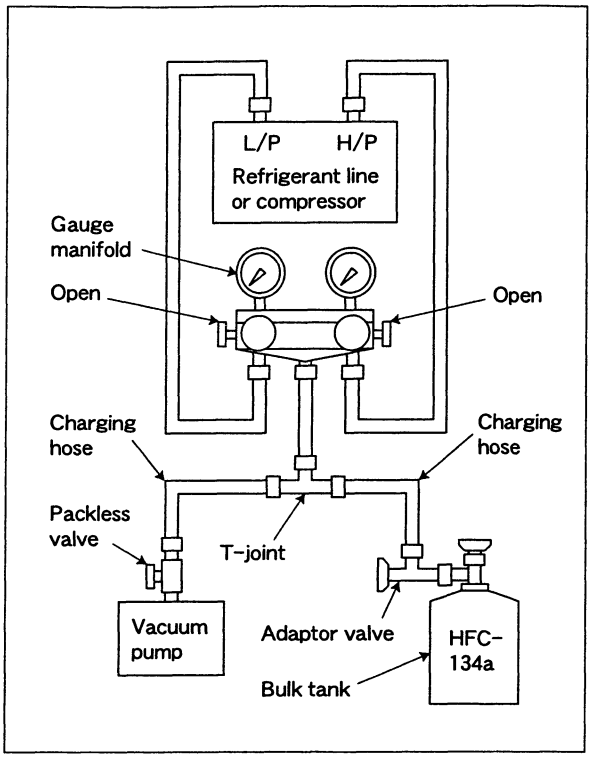
(1) Start up the vacuum pump.

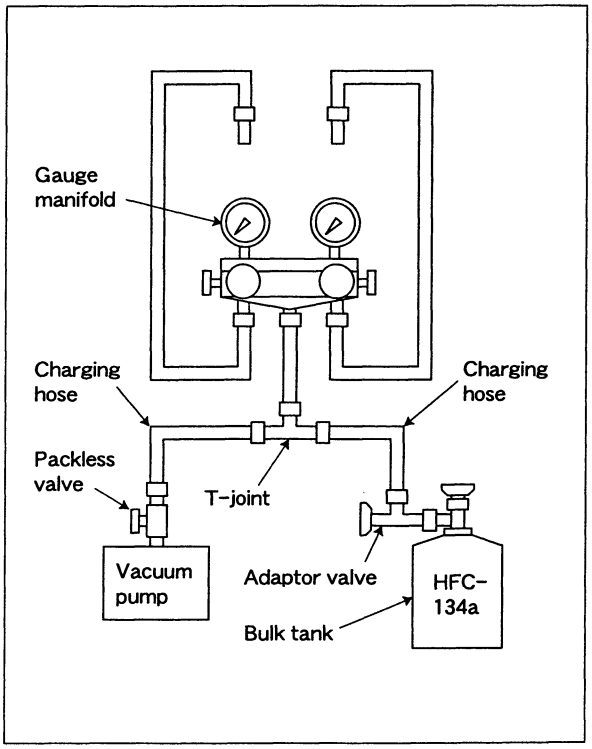
> ⚠ CAUTION
>
> 1. Do not use the compressor for evacuation.
> 2. Do not operate the compressor in the vacuum condition; damage may occur.

(2) Open the gauge manifold handles and the packless valve.
(3) Evacuate to a vacuum reading of 101kPa higher (approx.30 minutes).
(4) Turn back the packless valve all the way and close the bulk tank.
(5) Stop the vacuum pump and allow to stand for 5 minutes.
(6) Check for leak. (Good if the vacuum is held.)
(7) Tighten the charge valve handle to puncture the bulk tank.
(8) Open the charge valve to charge the system with refrigerant.
(9) When the refrigerant is no longer drawn in, turn back the high pressure side gauge manifold handles.
(10)Check for gas leaks using a leak detector.
(11)Start the engine.
(12)Operate the air conditioner and set at the lowest temperature (MAX. COOL).
(13)Fix the engine speed at 1500min^{-1}.
(14)Continue charging system until proper refrigerant quantity is introduced into the system.

> ⚠ CAUTION
>
> If the bulk tank is inverted, liquid refrigerant may be drawn into the compressor damaging it by liquid compression. Keep the bulk tank upright to ensure that refrigerant is charged in gas state.

(15)Upon completion of charging, turn back the low pressure side gauge manifold handles.





6.3.3 Removal of charge equipment

(1) Close the charge valve.
(2) Remove the gauge manifold from each service valves.

> ⚠ CAUTION
> Do not remove the bulk tank, T-joints and adaptor valves but keep them connected for next charge operation.

OPERATING LOW REFRIGERANT LEVEL

Locate the souce of the low refrigerant level, recover system, repair system, evacuate system, charge ststem, check for leaks.

> ⚠ CAUTION
> If the bulk tank is not emptied completely, keep the charge valve connected to the tank for next charging.

6.3.4 Discharging system

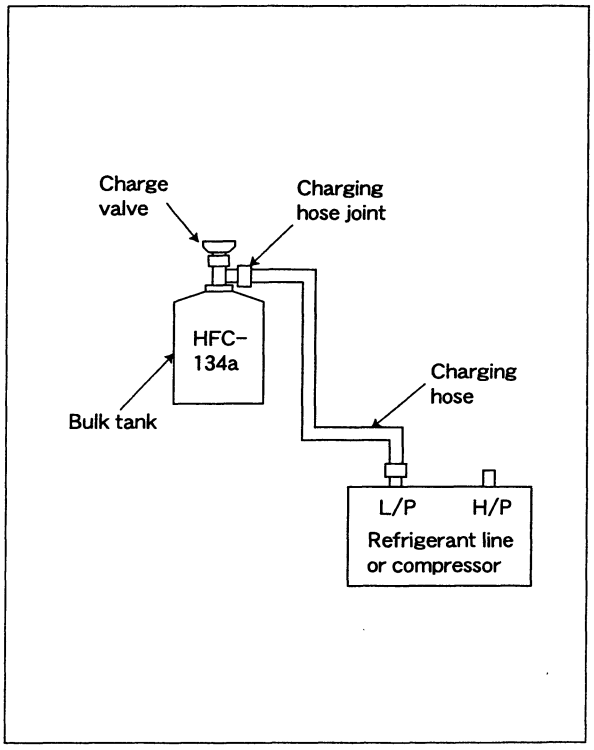
Use the refrigerant recovery unit which can be purchased in local market to discharge refrigerant gas from the system.

> ⚠ CAUTION
> Refer to that Refrigerant Recovery Unit Instruction Manual for operation which is attached on the unit.

LIQUID CHARGE, through high side using charging station:

> ⚠ CAUTION
> Do not run engine when performing liquid charge; compressor will be damage.

(1) After the system is evacuated, close gauge valves, connect center hose to refrigerant supply. Loosen center fitting at gauge to blow any air out of the hose and then retighten.
(2) Following charging station manufacture's instructions charge the system until 23oz of refrigerant is pumped into the system.
(3) When system is fully charged, close high gauge valve and refrigerant supply valve, then quickly disconnect gauge hoses from service
(4) After charging the system, refer to pre-delivery inspection.



6.4 Performance test

6.4.1 Preparation

Reinstall all vehicle parts that were removed for installation of the air conditioner at their original positions, adjust the mounting, and test the following items.

(1) Installation of grommets.

Install the specified grommets.

6.4.2 Stationary performance test

(1) Operating conditions

(a) Place the vehicle in the shade with doors open.

(b) Keep the return air temperature between 25 to 30℃, (Adjust by changing the opening degree of the doors).

(c) Set the fan switch to the max position.

(d) Turn the thermostat control lever to the cool position.

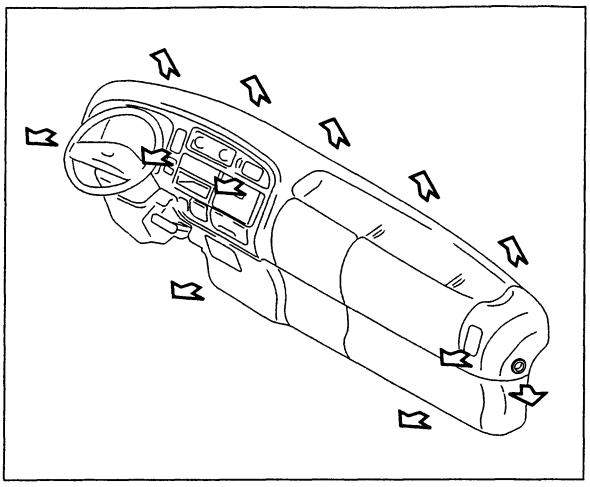
(e) Set the engine speed to approx. 1500min^{-1}.

(f) Set the high pressure at 1.17 to 1.37 MPa.

(If the high side pressure does not rise up, place paper or the like in front of the condenser.)

(2) Test procedure

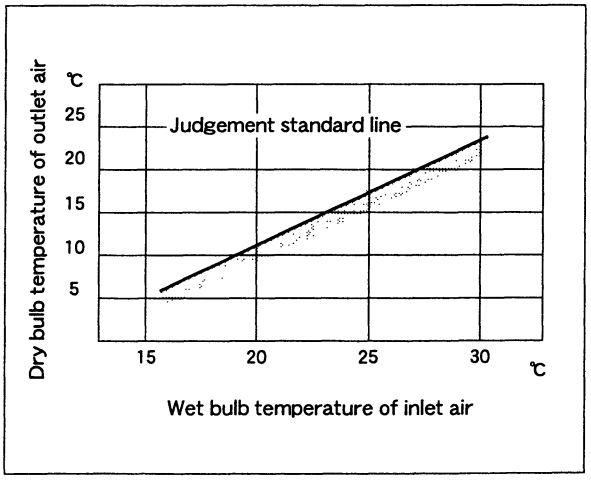
Operate the air conditioner for more than 10 minutes under the above operating conditions in order to stabilize the high and low pressures. Then perform the test by the following procedure:



(a) Measure the outlet air temperature at the inside space of the outlet grille.

(b) Measure the air conditioner intake air temperature, humidity, etc, and the items shown in the Table of Measuring Items at a position free from the effects of cool outlet air.

(c) The intersecting point of the plotted line perpendicular to the point which corresponds to the air conditioner intake and outlet air temperature difference and the plotted line perpendicular to the relative humidity of intake air should be between the oblique lines in figure.



7. MAINTENANCE

No.	Check point	Service and inspection intervals				
		When used only in summer (approx. for three months)		When used in all seasons		
		At the beginning or season	At the end of season	Every 5,000km (3,000miles)	Every 10,000km (6,000miles)	Every 20,000km (12,000miles)
1	Check condenser and radiator fin for clogging.	○	○	○		
2	Retighten all bolts.	○			○	
3	Check for refrigerant leaks.	○			○	
4	Check refrigerant level.	○		○		
5	Check V-belt tension.	○		○		
6	Check operation of magnetic clutch.	○			○	
7	Check operation of thermostat.	○				○
8	Cooling unit assembly performance test.	○		○		
9	Compressor overhaul.			Every four years		Every 40,000km (24,000miles)

⚠ WARNING

Even after the hot season is over, the air conditioner should be kept ready for operation all year round. Do not remove the V-belt or other parts.
This is because the air conditioner must be operated once a week for several minutes regardless of the season in order to prevent gas leaks caused by drying of the compressor shaft seal, and also to maintain the compressor itself in the best condition.

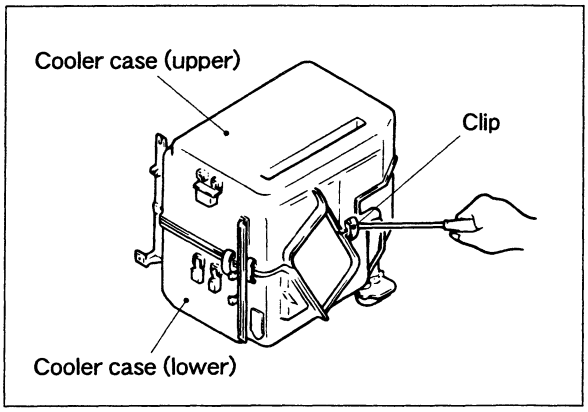
8.2 Cautions in disassembling

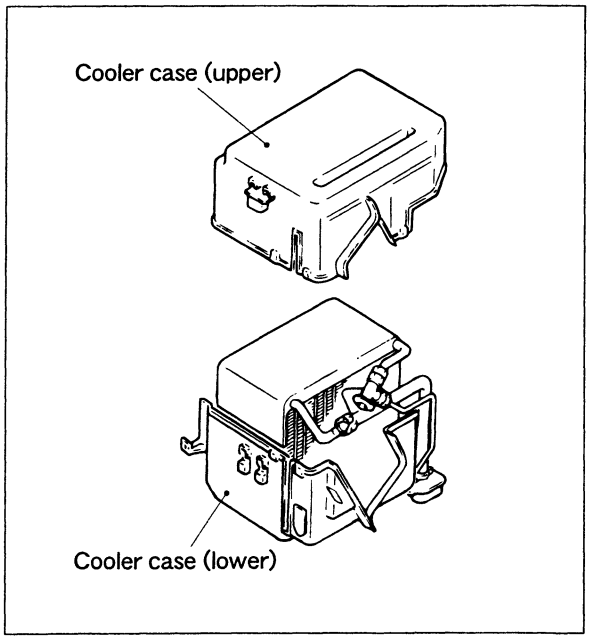
(1) Direct after disconnecting the refrigerant piping blind the opening to prevent dust and moisture etc. from eatering in it.
(2) When disconnecting the expansion valve, surely apply two spanners to prevent unstable twisting from applyng with the one for supporting and the other for torquing at the connection.
(3) Pipings in the cooling unit assembly should be handled gently. Particularly, the ingress and egress portions should be from any bending trouble in carrying it.
(4) If the cooling unit assembly is stored, or transported on disassembled condition, be careful not to deform the fins.
(5) When disconnecting the wiring, avoid pulling it with the insulation cover catched, but apply force by pinching the terminals or by catching the connectors.

8.3 Disassembling

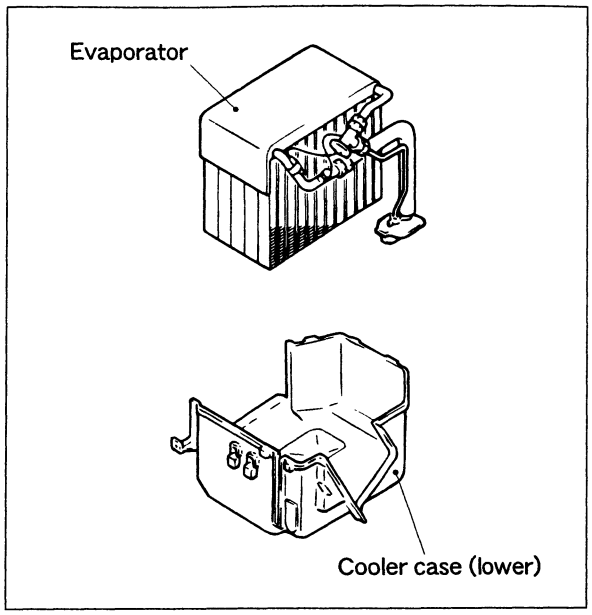
(1) Remove the clips for jointings the upper & lower side cooler case with a flat type screwdriver.



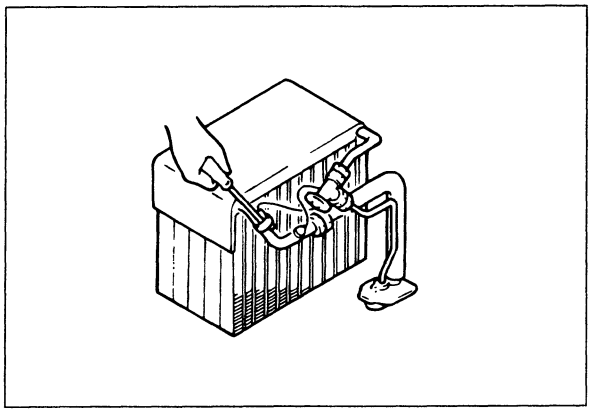
(2) Dismount the cooler case (upper).



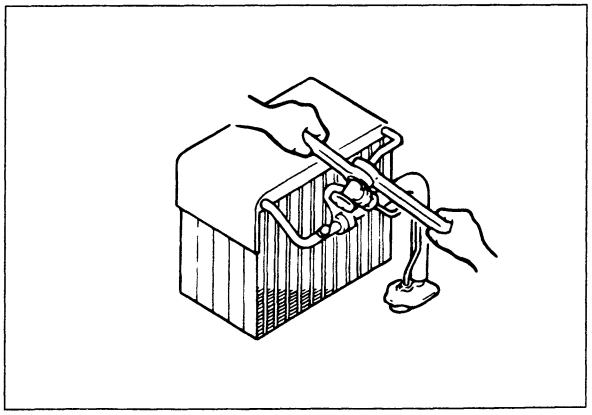
(3) Dismount the evaporator.



(4) Separate the expansion valve.
Dismount the feeler bulb at the suction side.

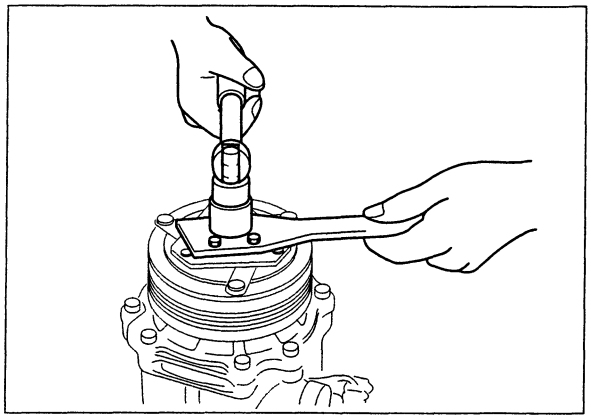


(5) Dismount the expansion valve from the circuit.

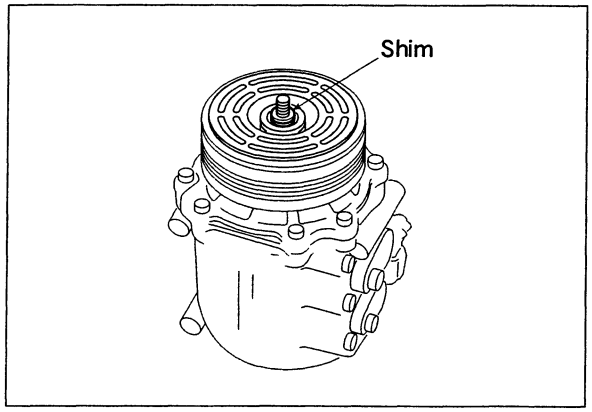


9. COMPRESSOR & CLUTCH ASSEMBLY

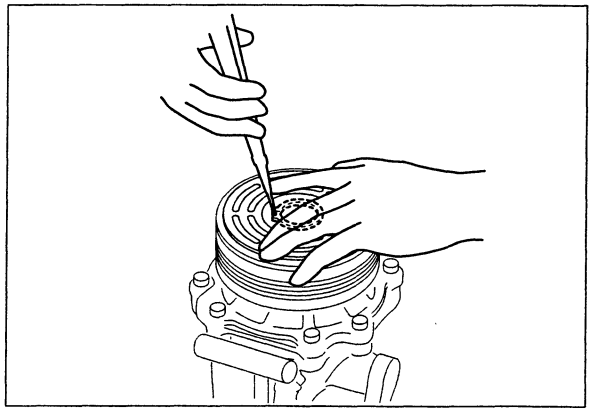
9.1 Disassembling the clutch



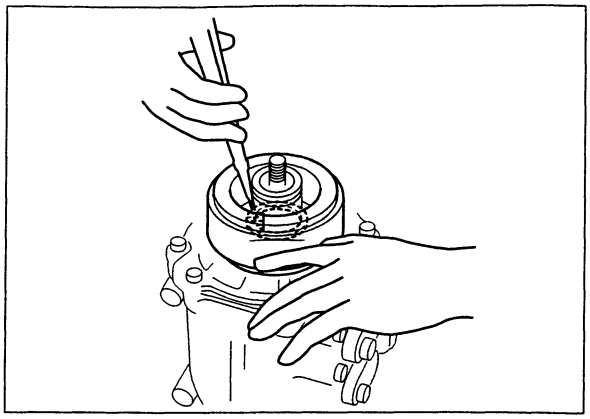
(1) Removal of armature plate.
  (a) Lock up the armature plate with a armature plate fixture and remove the lock nut.
  (b) Remove the armature plate.



(2) Remove the shim.



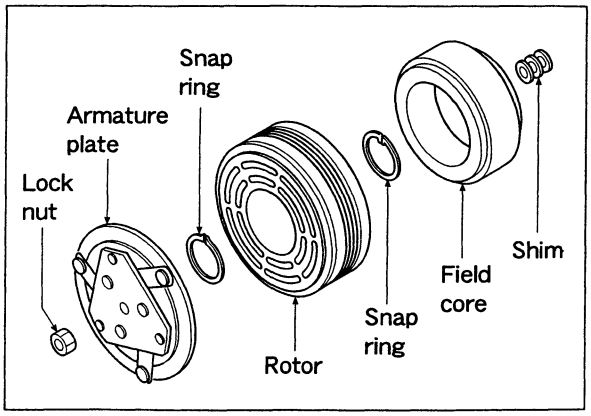
(3) Withdrawing rotor.
  (a) Remove the snap ring at the front case side with snap ring pliers.
  (b) Withdraw the rotor toward you and remove it from the front case.



(4) Removal of field core.
  (a) Remove the snap ring for fixing the field core with snap ring pliers.

  (b) Remove the ground wire with a cross point screwdriver and withdraw the field core toward you to remove it from the crank case.

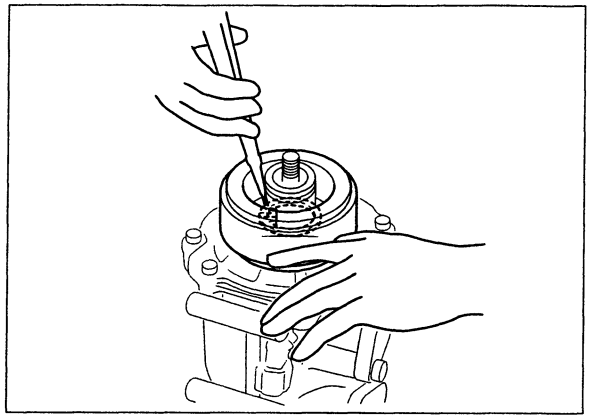
(5) Removal of key.
  Remove the key from the shaft using the top of a flat type screwdriver.



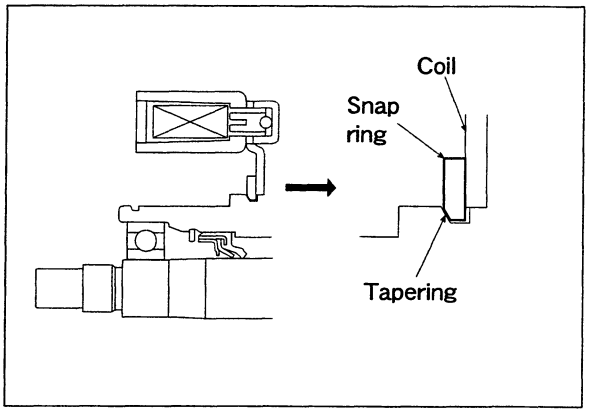
(6) Components of magnetic clutch.

9.2 Reassembly the clutch

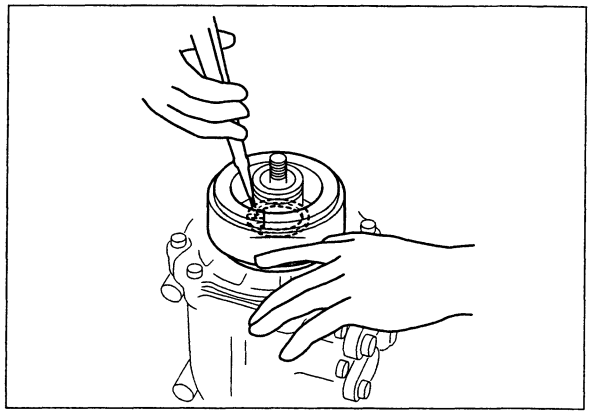
(1) Insert the key into the clankshaft.
(2) Insert the field core.



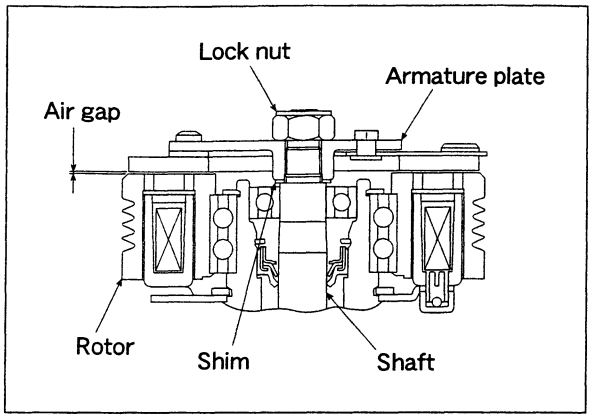
(a) Insert the field core into the front case and position it with a knock pin.
(b) Insert the snap ring for fixing field core into the groove and fix it with snap ring pliers as shown the below.



(c) Connect the ground wire.
(3) Insert the rotor into the front case.



(4) Insert the snap ring for the front case side into the groove with snap ring pliers.



(5) Insert the armature plate.
(a) Place a shim on the end of the shaft and insert the armature plate, adjusting to the key.
(b) Tighten the center bolt to the specified torque, 15.7N.m, with in between plain washer.
(c) Measure the air gap.
The air gap should be within 0.4 to 0.65 ㎜.
Adjust it by shim if it is not within the specifications.
Adjusting shim : 0.1, 0.3, 0.5, or 0.8 ㎜.

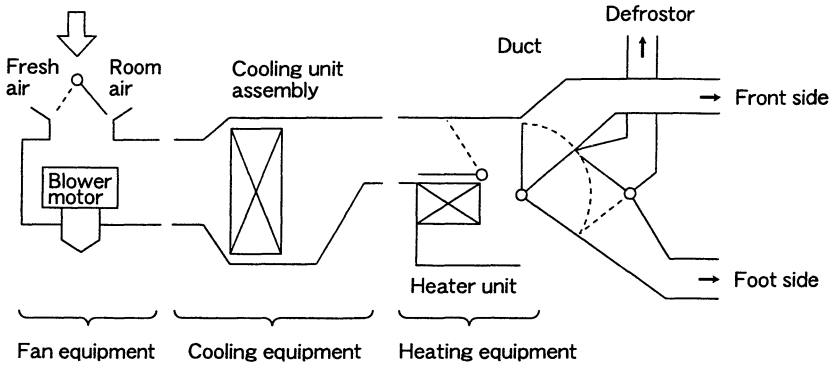
2. OUTLINES OF REFRIGERATION SYSTEM

2.1 Air system



Cooling operation

Fresh air is induced to the cooling unit assembly by a blower fan, where it is cooled down and dehydrated, charged at the front side outlet through a duct.

Heating operation

Fresh air is induced to the heater unit by a blower fan through the cooling unit assembly, where it is heated, then discharged at the foot side outlet through a duct.

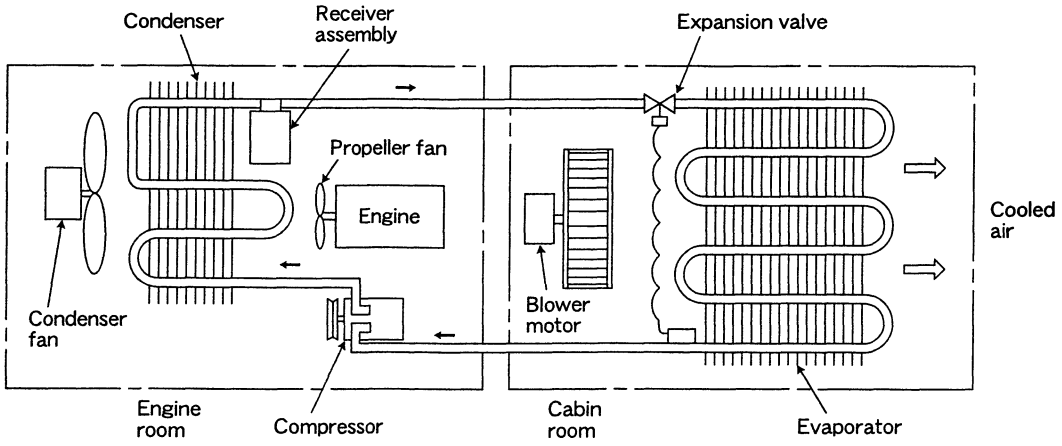
Dehumidifying operation

Fresh air is induced to the cooling by a blower fan, where it is cooled down and dehydrated, and succeedingly to the heater unit for warming, then discharged at the front side outlet through a duct.

Temperature control

Cooled air and warmed air are mixed for temperature control of the room inside.

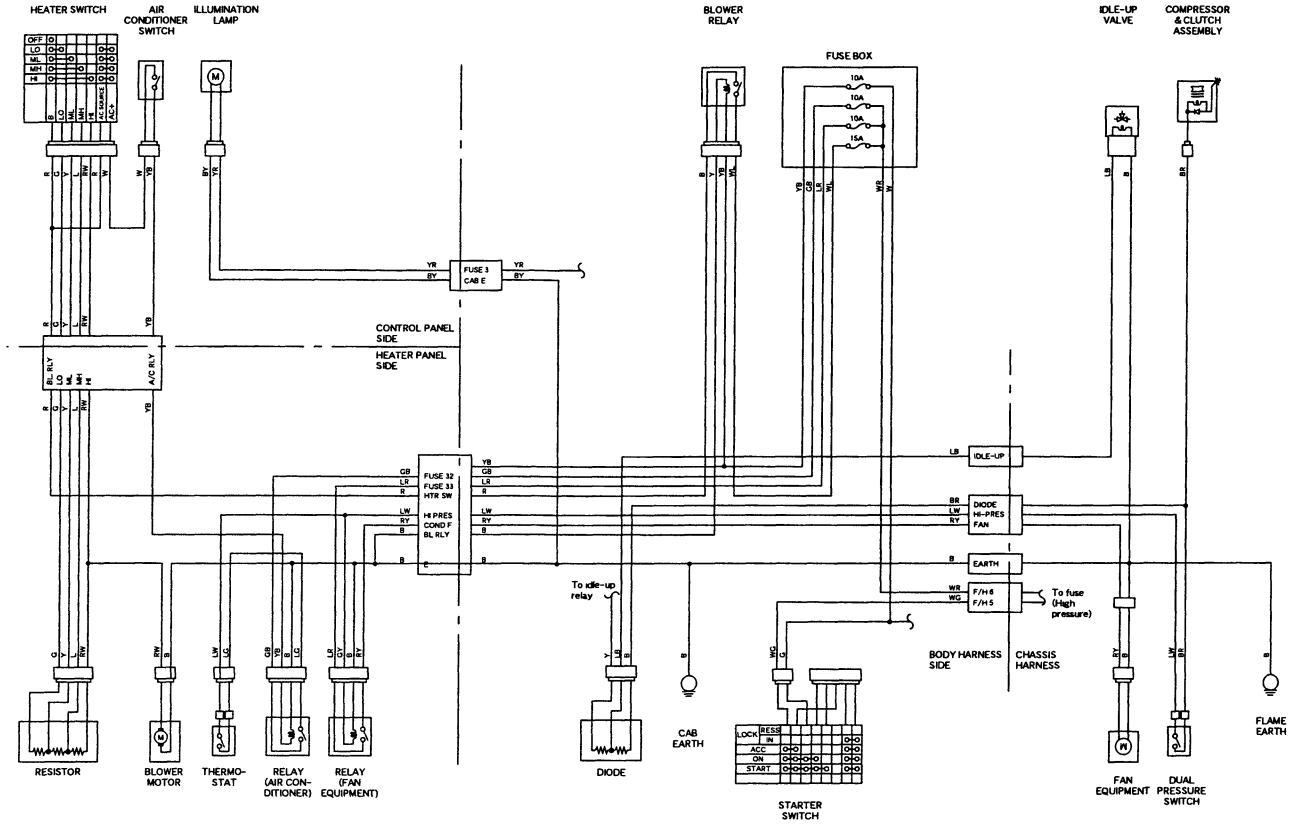
2.2 Refrigerating circuit



While the refrigerant, HFC-134a is cooling the air drawn into the evaporator, it evaporates and becomes a gas. This gas is compressed to high pressure and temperature in the compressor, and sent into the condenser, where it is cooled and becomes liquid.
This cooling in the condenser is carried out by the open air passing through the condenser sucked by radiator fan and vehicle motion of the vehicle.
The liquid refrigerant flows through the receiver assembly where water and dirt are removed, and then it enters the expansion valve. Here the liquid refrigerant is throttled and changed to a mixture of liquid and gas in low temperature and low pressure, and is sent to the evaporator.

In the evaporator, the refrigerant absorbs heat from the surroundings and becomes a gas. That is, because the evaporator it self is cooled at this time, the return air to the cooling unit assembly is cooled,
and the interior of the vehicle becomes cool. In this way the refrigerant flow makes a complete circuit.

2.3 Electrical system



The power source is supplied from the TRUCK battery. When the blower switch is put ON, the power relay becomes ON, and electricity is connected to the magnetic clutch of the compressor. The magnetic clutch switches ON or OFF by air conditioner switch, fin thermo, and low pressure switch as the controls for operation service, or safety protection.

The cabin room air temperature is set to a preset point by adjusting the temperature control lever, and the opening degree of the air mix damper.

3.3 Control system

(1) Control in panel

Do not run the air conditioner when it is child.

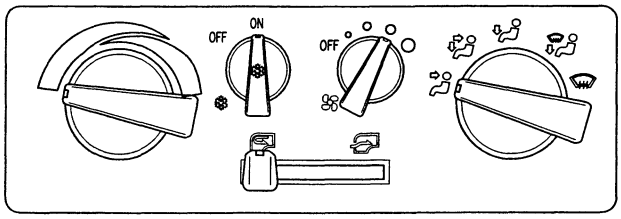
☐ Air conditioner switch
By select the air conditioner switch initially in cooling or drying operation, the compressor starts running.

☐ Fan switch
The air flow is selectable, out of the below four volume.

OFF	No air flow
◦	Gentle
o	Low
o	Medium
O	High

☐ Air outlet mode select switch
The air outlet is selected by positioning in cooling and heating operation.

- ----- The conditioned air is discharged at the center and both side outlets directed by the louvers as reguired.
- ----- The conditioned air is discharged at the center and both side and foot outlets directed by the louvers as reguired.
- ----- The conditioned air is discharged at the foot outlets directed by the louvers as reguired.
- ----- The conditioned air for dehumidifying is discharged at the foot outlets and to the front glass.
- ----- The conditioned air for dehumidifying is discharged to the front glass.



☐ Temperature control switch
The discharged air temperature is controllable by selecting the position of the control lever in cooling, heating or drying operation.

BLUE ZONE ------ For cool air flow
RED ZONE ------- For warm air flow

By turning the switch toward the BLUE and RED ZONE sides, the supply air temperature becomes more cooler and warmer respectively.

☐ Shift lever, air circulation
The recirculation air is selectable out of the below circulation modes.

- ----- Room circulation
- ----- Fresh air intake

(2) Operation control

Operation mode	Setting control lever	Air delivery	Remarks
COOL			Earlier cooling service, or conditioning at dusty, polluted air prevailing places : Shift lever : Air circulation

⑭ Needle bearing

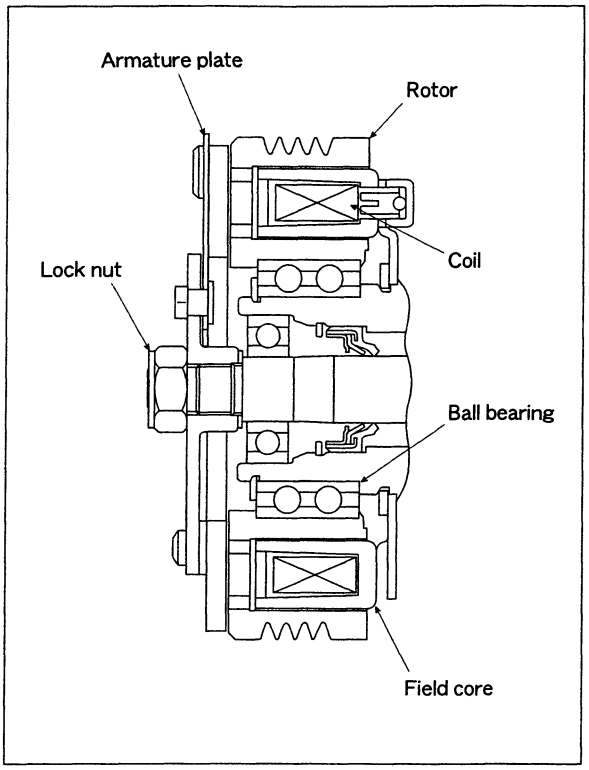
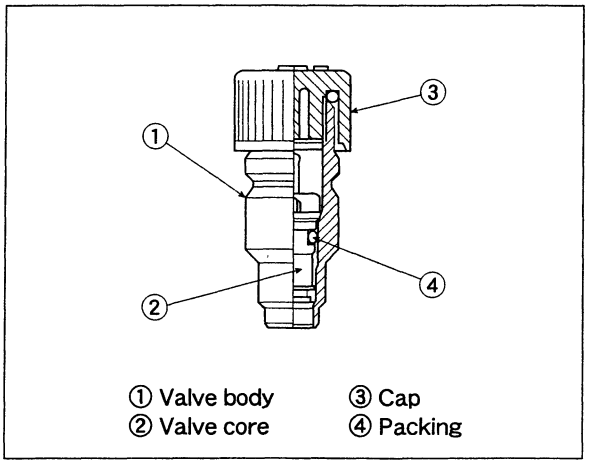
3.4.2 Magnetic clutch



The magnetic clutch is mounted on the compressor crankshaft to start and stop the compressor.
This means that the magnetic clutch is actuated to control the compressor operation electrically by the thermostat.

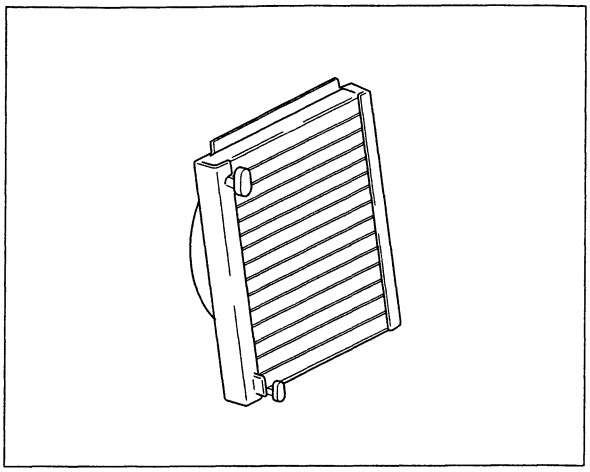
3.5 Check valve



① Valve body ③ Cap
② Valve core ④ Packing

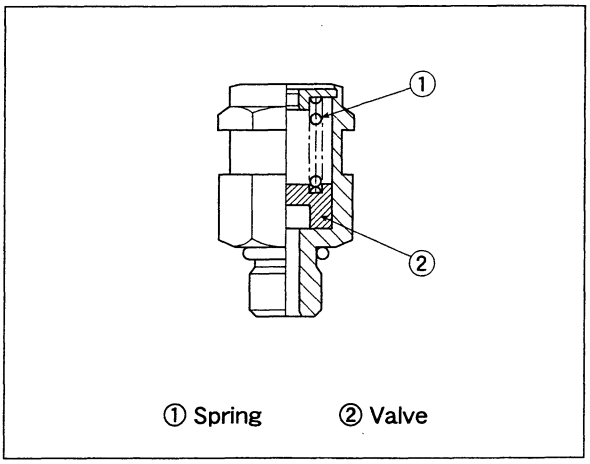
The suction hose and discharge hose are provided with check valve, and designed for gas evacuation and charging service. (shown above)
In the valves, a valve rubber tube, as in automobile tire tubes, is provided as shown in the figure.
Stackening the flare nut on the gauge manifold causes the passege to close automatically by the spring force, and tightening the flare nut causes the passege to open while pressing the compressed spring.

3.6 Side condenser assembly



The condenser is a means to liquefy the refrigerant gas. As the condenser is cooled by the air pulled in by the condenser fan, the refrigerant in the condenser is cooled into liquid. Therefore, when any obstacle prevents the air from flowing evenly to the condenser or the air flow is short circuited, the cooling effect is reduced, with a decrease in the performance of the condenser. When the vehicle is driven at a high speed, the air flow increases resulting in an increase of the cooling effect, and performance of the condenser.

3.7 Relief valve



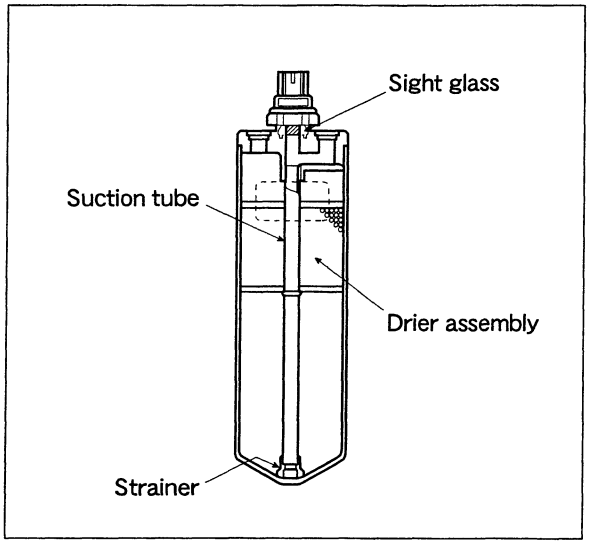
① Spring ② Valve

The relief valve is mounted to the compressor & clutch assembly. The relief valve is usually closed by spring. If pressure of refrigerant in air conditioner system is higher than spring pressure, refrigerant is discharged from relief valve. The pressure drop due to discharge refrigerant, and relief valve is closed again.

Unit : MPa

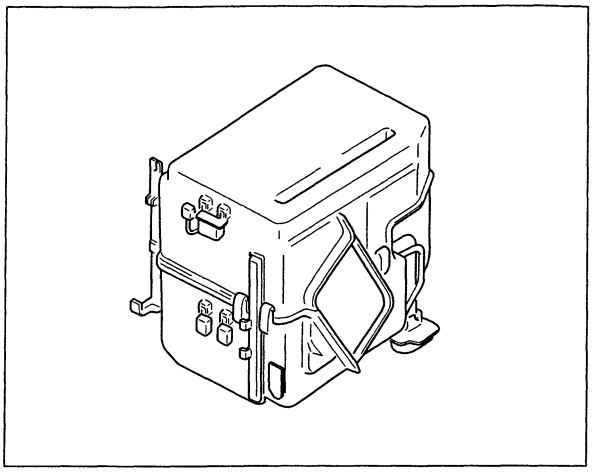
Open	3.50~4.10
Close	2.94

3.8 Receiver assembly



The receiver assembly is served as a refrigerant reservoir located between the condenser and expansion valve. The receiver assembly consists of a filter and a sight glass. The filter is used to remove dust , the drier is used to remove moisture from the refrigerant in the circuit, and the sight glass is used to check the refrigerant charge. Any moisture in the refrigerant may not only corrode metal surfaces in the refrigerant circuit, but also cause the throttle of the expansion valve to be frosted, resulting in the interruption of refrigerant circulation.
Therefore, the receiver assembly must be handled very carefully. When storing or installing it, care should be taken to protect it from the deterioration of drying performance due to exposure to the air.
The retardation of heat exchange, or any fire around the refrigerant circuit will cause excessive pressurization or heating of the refrigerant. Should such an accident occur, the refrigerant in the circuit must be expelled to the outside to prevent the above hazards.
The sight glass is a sort of peep window used to check the refrigerant flow in the refrigerant circuit.
The sight glass appears clear when the refrigerant flow is enough, and shows bubbles flowing when the refrigerant flow is short.

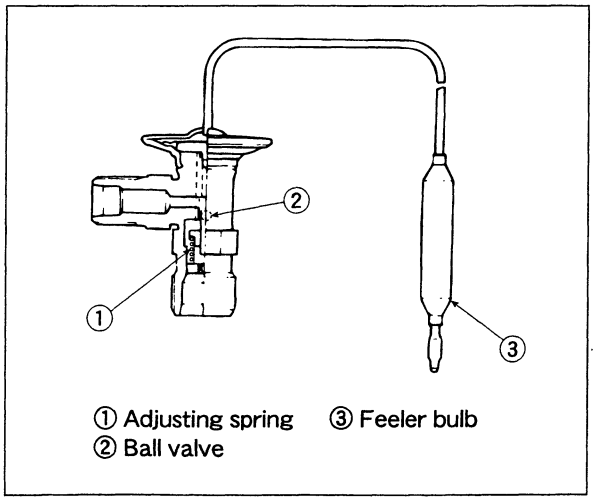
3.9 Cooling unit assembly



The evaporator core is a type of corrugated fin and tube. The tube is arranged in zigzag to achieve high effciency, and to make the core system compact.
A thicker reinforced plastic plate is used as the enclosure to inclease heat and shock resistance, and to protect the core from humidity. This case is a split type, and in a simple design to facilitate installation on the floor panel and the instrument panel frame of the vehicle.

3.10 Expansion valve

The expansion valve is mounted at the inlet of the cooling unit. The liquid refrigerant from the receiver is led to it through a narrow passage (for throttle action), where-in, the liquid refrigerant is condensed with pressure dropping and at the same time the flow rate is adjusted before the refrigerant is sent to the cooling unit.
The refrigeration load in the cooling unit is not constant, but usually fluctuates over a certain range. So the refrigerant flow should under go the control in design.
An automatic expansion valve performs this function automatically. The air condenser uses a thermal type automatic expansion valve.



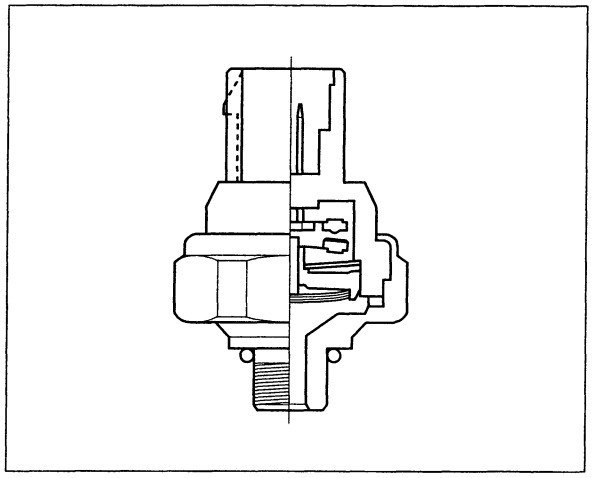
① Adjusting spring ③ Feeler bulb
② Ball valve

3.11 Dual pressure switch

The dual pressure switch, fixed to the receiver functions as a protector for stopping the compressor (OFF) at a preset value of pressure in the refrigerant circuit.

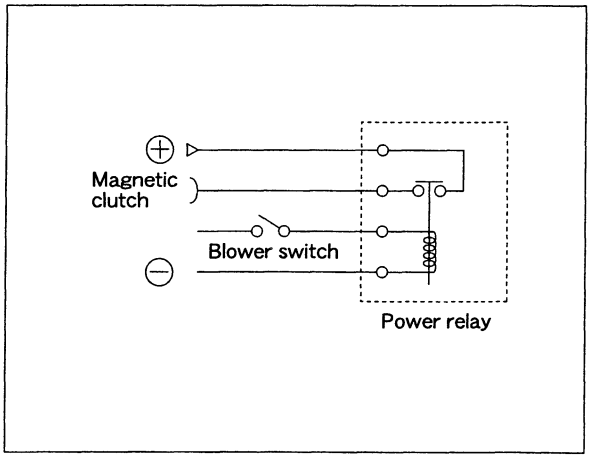
Unit : MPa

	LP side	HP side
OFF	0.2	2.94
ON	0.22	2.35



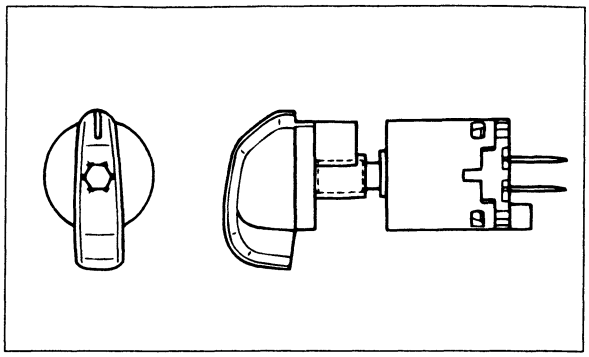
3.12 Power relay

The power relay is excited at a closed position of the micro switch and enables the magnetic clutch to be ready for engaging electically.



3.13 Air conditioner switch

The air conditioner switch function as an operation controller for starting or stopping the compressor in cooling and dehumidifying.
Set the it to the "ON" position, the magnetic clutch becomes engaged and the compressor starts.
Set the it to the "OFF" position, the magnetic clutch becomes disengaged and the compressor stops.

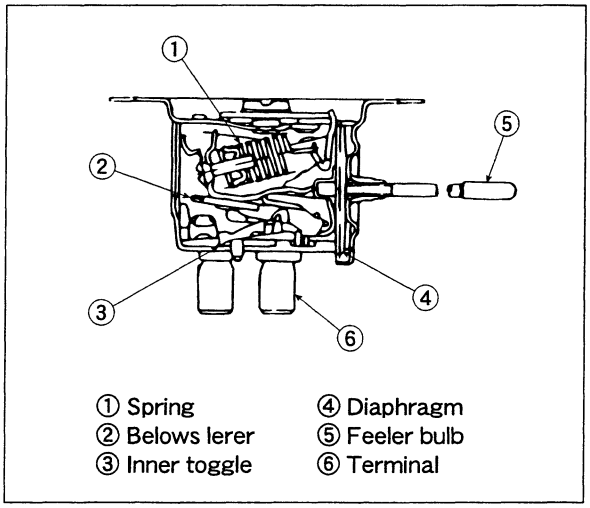


3.14 Thermostat

The thermostat is mounted on the evaporator case. It senses the temperature of evaporator fins, and controls the compressor operation for ON or OFF as specified below.

Unit : ℃

OFF	33
ON	38



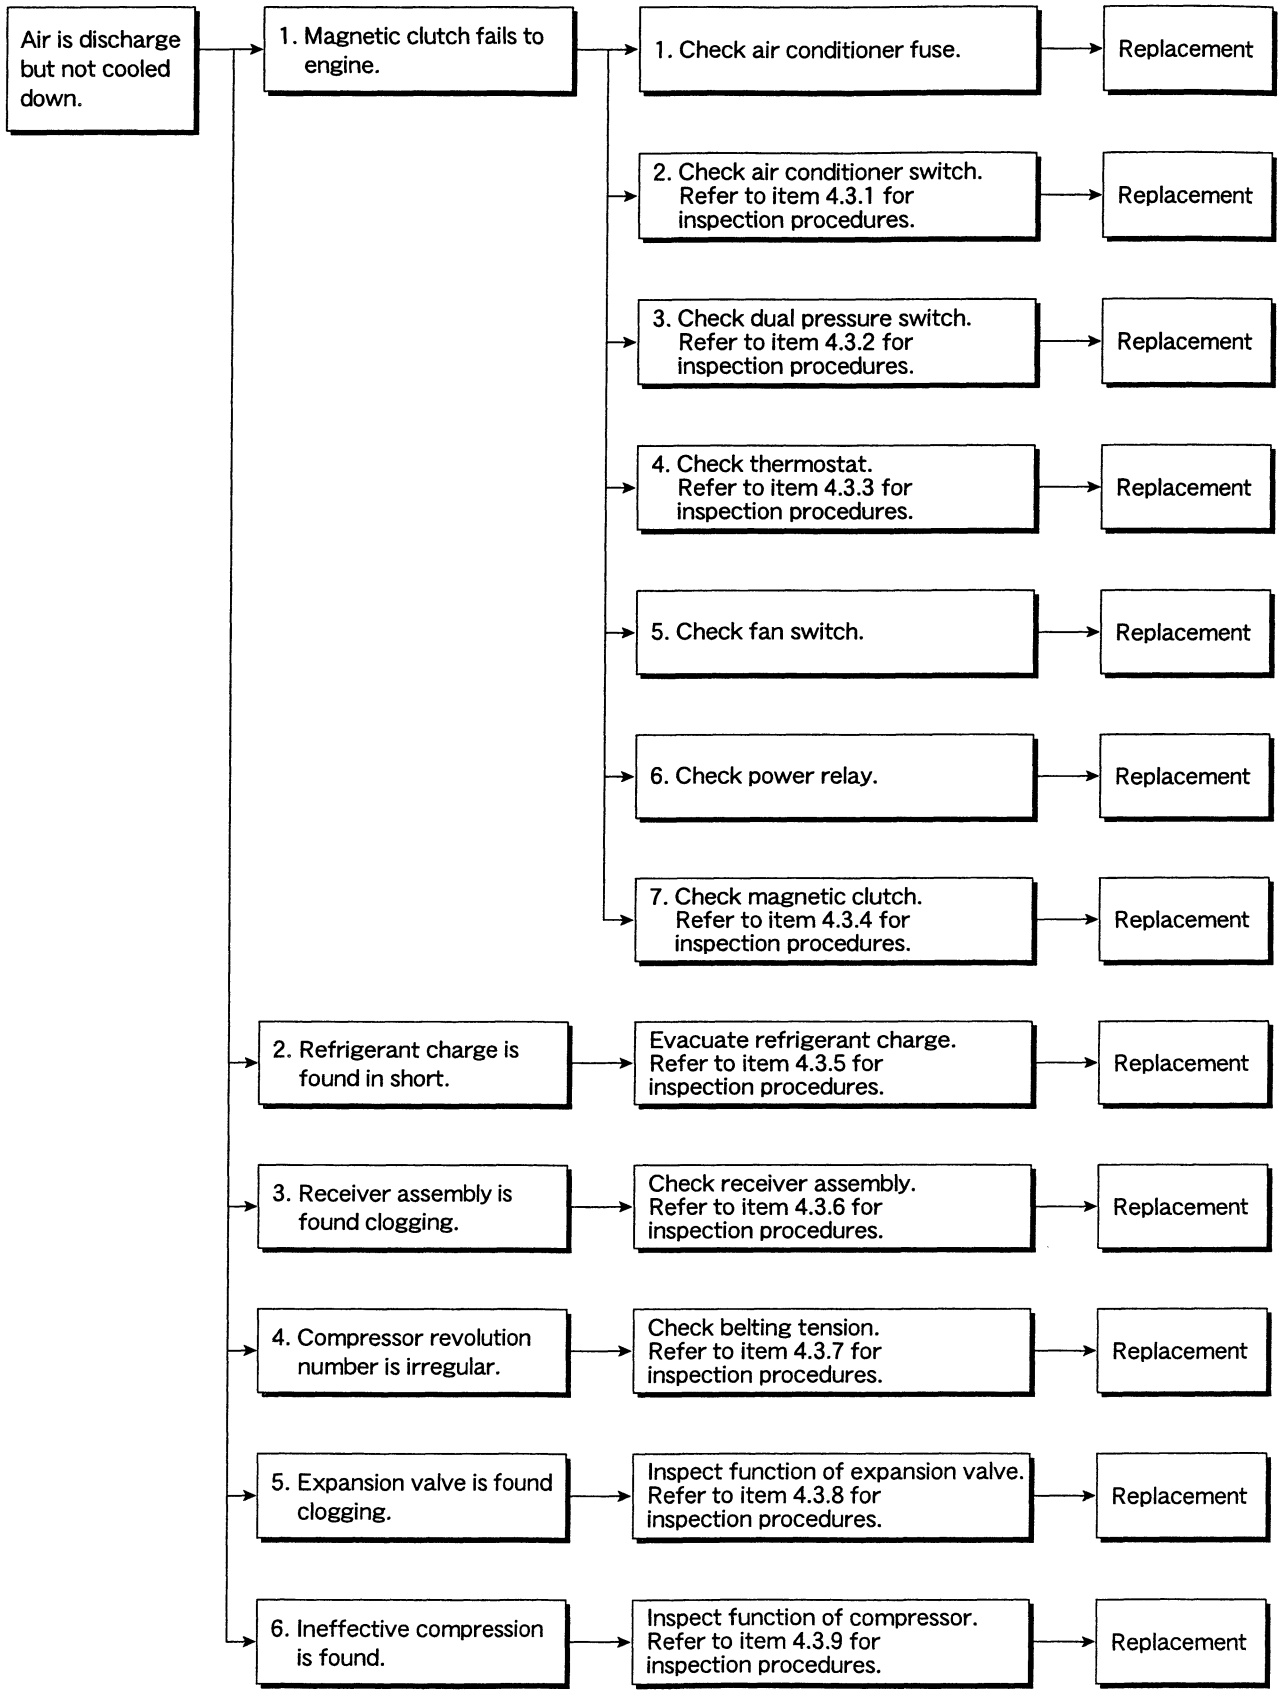
4 . TROUBLE SHOOTING

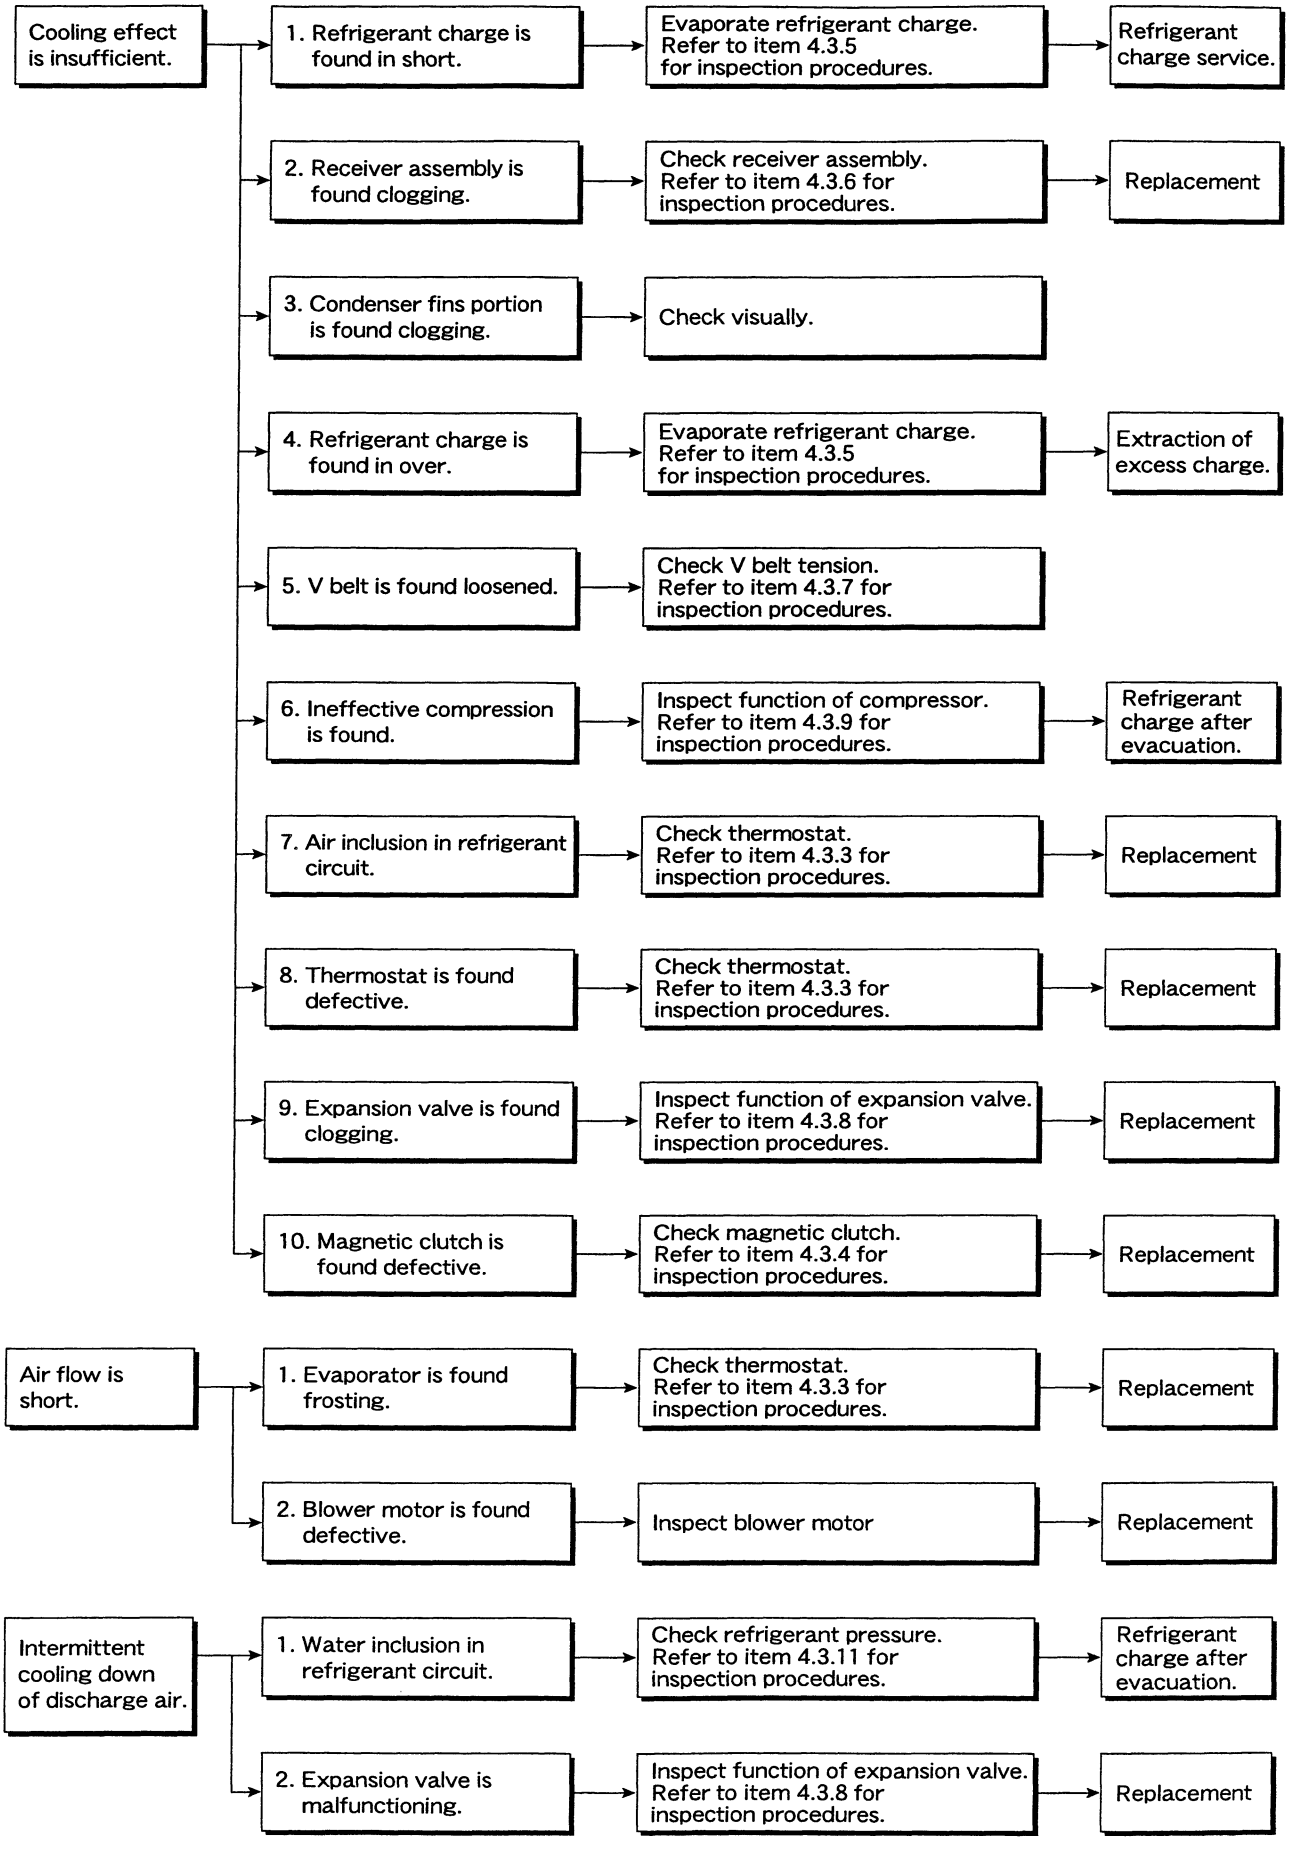
4.1 General precaution

(1) When handling refrigerant (HFC-134a), the following precautions must be observed.
   a. Allways wear eye protection and a pair of gloves which handling refrigerant.
   b. Be careful the liquid refrigerant dose not contact the skin.
   c. Keep the refrigerant container blow 40 degrees C.
   d. Do not handle the refrigerant in an enclosed area having an open flame. The refrigerant may produce a poisonous gas.
   e. When dumping the refrigerant from the system, release it slowly so as not to expell all the compressor oil.

(2) If liquid refrigerant strikes eye or skin.
   a. Do not rub eye or skin.
   b. Splash large quantities of cool water on the eye or skin.
   c. Rush to a physician or hospital for immediate professional treatment.

4.2 Trouble cause and remedy





Cooling effect is insufficient.
1. Refrigerant charge is found in short.
Evaporate refrigerant charge. Refer to item 4.3.5 for inspection procedures.
Refrigerant charge service.
2. Receiver assembly is found clogging.
Check receiver assembly. Refer to item 4.3.6 for inspection procedures.
Replacement
3. Condenser fins portion is found clogging.
Check visually.
4. Refrigerant charge is found in over.
Evaporate refrigerant charge. Refer to item 4.3.5 for inspection procedures.
Extraction of excess charge.
5. V belt is found loosened.
Check V belt tension. Refer to item 4.3.7 for inspection procedures.
6. Ineffective compression is found.
Inspect function of compressor. Refer to item 4.3.9 for inspection procedures.
Refrigerant charge after evacuation.
7. Air inclusion in refrigerant circuit.
Check thermostat. Refer to item 4.3.3 for inspection procedures.
Replacement
8. Thermostat is found defective.
Check thermostat. Refer to item 4.3.3 for inspection procedures.
Replacement
9. Expansion valve is found clogging.
Inspect function of expansion valve. Refer to item 4.3.8 for inspection procedures.
Replacement
10. Magnetic clutch is found defective.
Check magnetic clutch. Refer to item 4.3.4 for inspection procedures.
Replacement
Air flow is short.
1. Evaporator is found frosting.
Check thermostat. Refer to item 4.3.3 for inspection procedures.
Replacement
2. Blower motor is found defective.
Inspect blower motor
Replacement
Intermittent cooling down of discharge air.
1. Water inclusion in refrigerant circuit.
Check refrigerant pressure. Refer to item 4.3.11 for inspection procedures.
Refrigerant charge after evacuation.
2. Expansion valve is malfunctioning.
Inspect function of expansion valve. Refer to item 4.3.8 for inspection procedures.
Replacement

4.3 Inspection procedure

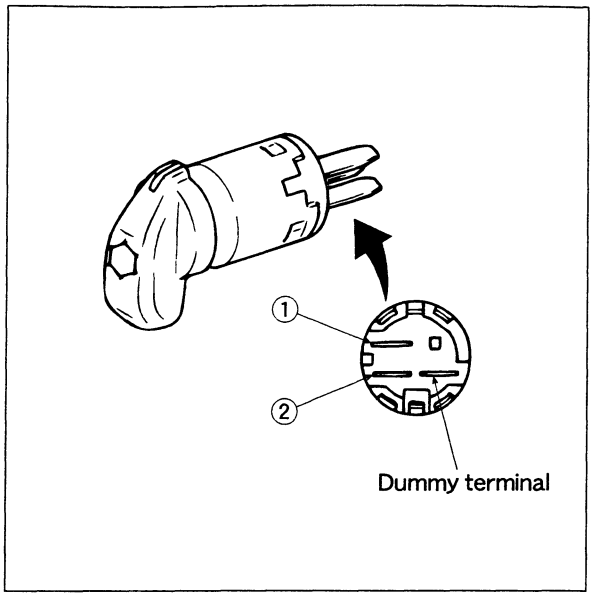
4.3.1 Air conditioner switch

(1) Unplug the air conditioner switch.
(2) Check the continuity between terminals of the air conditioner switch with a tester.

Continuity

Switch position	Terminal's number	Result, in normal
OFF	①-②	No
ON	①-②	Yes

Switch position \ Terminal's number	1	2
OFF	○	
ON	○	○

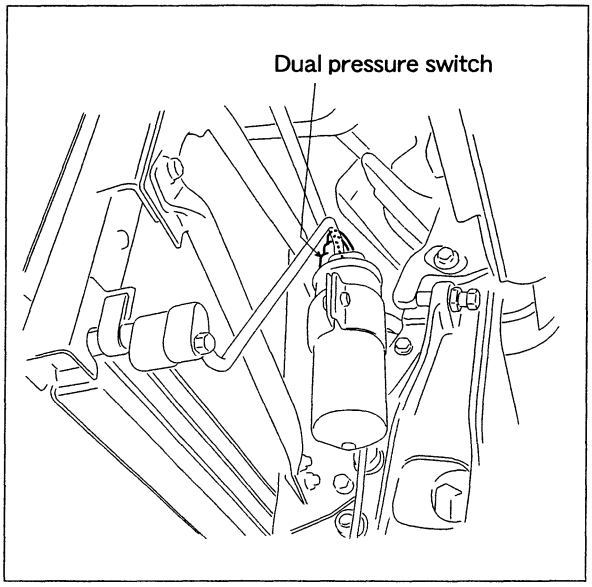


4.3.2 Dual pressure switch

The dual pressure switch is attached to the receiver assembly for controlling the operation of the air conditioner by checking the inside pressure of the receiver assembly.

Unit : MPa

	LP side	HP side
OFF	0.2	2.94
ON	0.22	2.35



(1) Unplug the connector at the receiver assembly.
(2) Check the continuity between terminals of the connector with a tester.
(3) When electric continuity is found, connect the connector to the high pressure switch.
(4) Attach the high pressure gauge and low pressure gauge.
(5) Operate the air conditioner.
(6) Cover the surface of the condenser by using a piece of paper.
(7) When the high pressure exceeds 2.94 MPa, if the magnetic clutch is turned off, the switch is normal.
(8) If the magnetic clutch is not turned off, replace pressure switch with new one.
(9) Check the accuracy of the preset as below.
  (a) Stop the air conditioner.
  (b) Purge the air conditioner of refrigerant slowly starting at over 0.22 MPa.
  (c) At reading the pressure 0.2 MPa, the switch opens.
  (d) Here, stop the purging, then turn it to charging.
  (e) At reading the pressure 0.22 MPa, the switch closes.

If the dual pressure switch does not meet specifications, replace the switch.

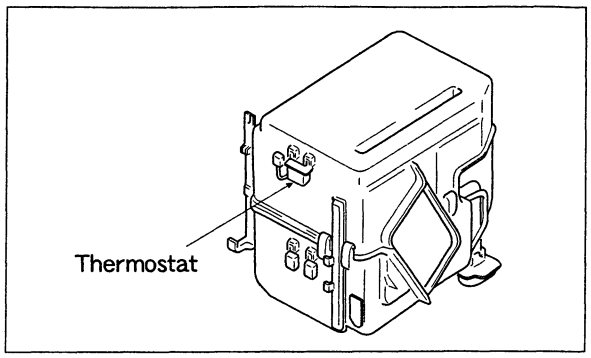
4.3.3 Thermostat

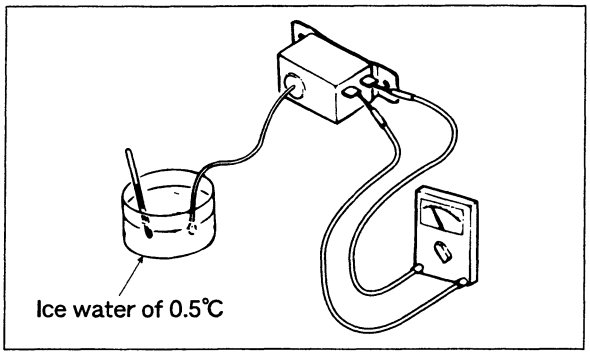
The thermostat is mounted on the evaporator case. It controls the operation of the air conditioner by sensing the temperature of the evaporator fins.

Unit : ℃

OFF	0.5
ON	3.5

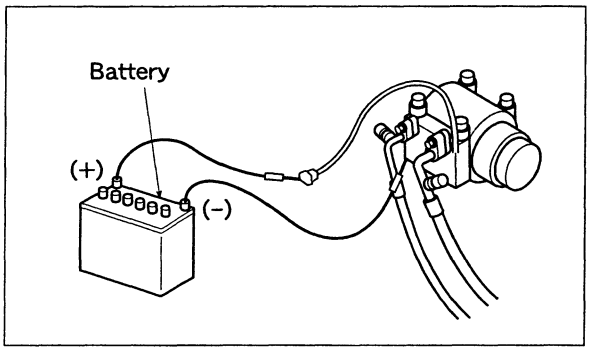
(1) Check the accuracy of the preset as below.
  (a) Soak the sensor of the thermostat in ice-water of below 0.5℃.
  (b) Check the continuity between the switch terminals.
  (c) Pull the senser out of the ice-water, and check the continuity at over 3.5℃ of the senser.





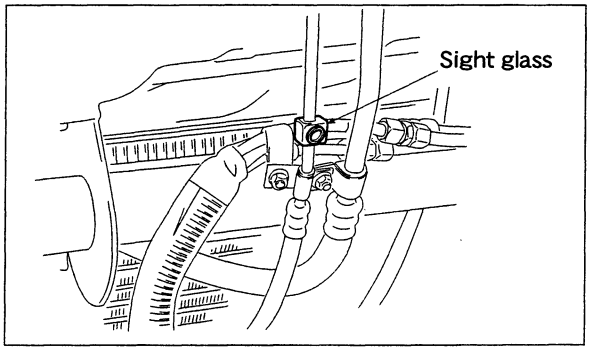
4.3.4 Magnetic clutch

(1) Disconnect the wiring to the magnetic clutch.
(2) Apply a positive side power voltage to the magnetic clutch through the wiring.
(3) In the case of regular functioning, the pulley and magnetic clutch are engaged with a clicking sound. The falling means any malfunction of the magnetic clutch.



4.3.5 Refrigerant charge

(1) Set the temperature control lever at the cool position.
(2) Open doors of the room.
(3) Set the blower switch at the ON position.
(4) Adjust the engine revolution at 1500min^{-1}.
(5) Operation the air conditioner switch for comp. ON.
(6) Watch the sight glass of the liquid hose at the inside of the engine room.
  (a) If judged insufficient refrigerant charging, repair the leaks, then charge it additionally.
  (b) If judged as over charging of refrigerant, extract an excess refrigerant.
(7) Diagnosis by pressure reading.
  (a) Short of refrigerant:
    Lower pressure for both LP and HP reading.
  (b) Express of refrigerant:
    Higher pressure for LP and HP reading.

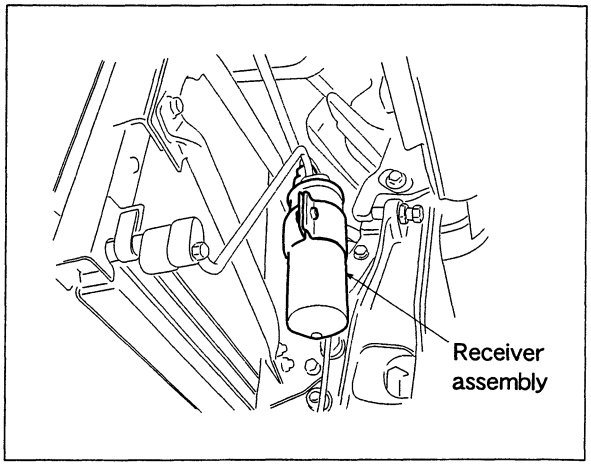


Sight glass		Remarks
Proper refrigerant level	Bubble	1. Bubble occasionally appears. 2. Bubble disappear if speed is a little increased.

Sight glass		Remarks
Insufficient refrigerant	Bubble	Considerable bubbles appear. If the system is extremely short of refrigerant, the sight glass appear white.
Excessive refrigerant		1. No bubbles appear. 2. Slight bubbles appear if speed is decreased.

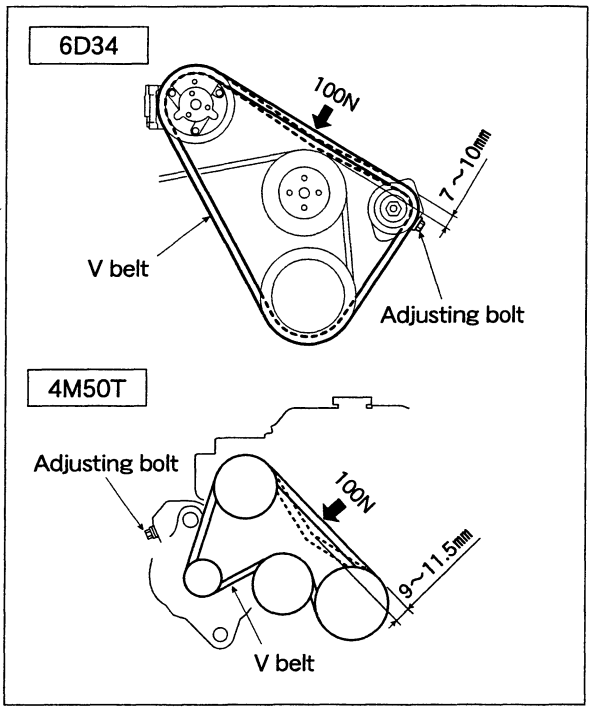
4.3.6 Receiver assembly

(1) While operating the air conditioner, touch the refrigerant piping with a hand at the inlet and outlet portions.
  (a) Sensed temperature difference:
    It is possible that clogging is happening at the inside, liquid receiver assembly is to be replaced with a new one.



4.3.7 Belt tension

(1) Depress the V belt with a thumb at the ⬅ marked position, and adjust the stretching as below.
  Stretching degree : 6D34 / 7～10 ㎜
    4M50T / 9～11.5 ㎜
(2) Adjustment
  (a) Loosen the nut of the tension pulley.
  (b) Control the belting tension by the adjusting bolt.
  (c) After finishing, retighten the nut as before.

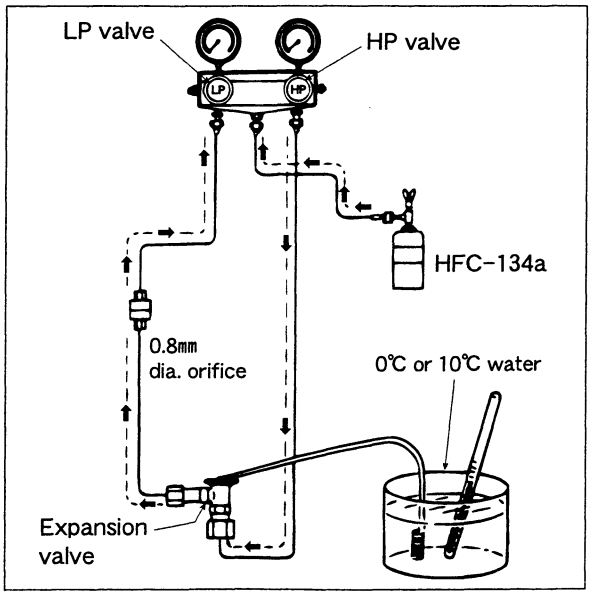


4.3.8 Expansion valve

⚠ CAUTION

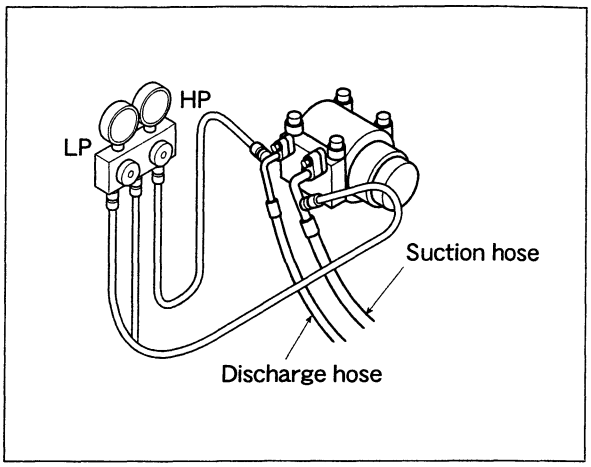
The test should be applied to only the case of the other components being free from troubles, and the expansion malfunctioning singly.

(1) Build up the test circuit with a gauge manifold.
(2) Soak the sensor bulb in ice water of 0℃, and of 10℃ respectively.
(3) Pressurize the HP side with dry nitrogen gas of 1.03MPa.
(4) Check the reading of the LP side pressure gauge for the standard range.
  At 0℃ ····0.127MPa
  At 10℃ ····0.23MPa



4.3.9 Pressure check

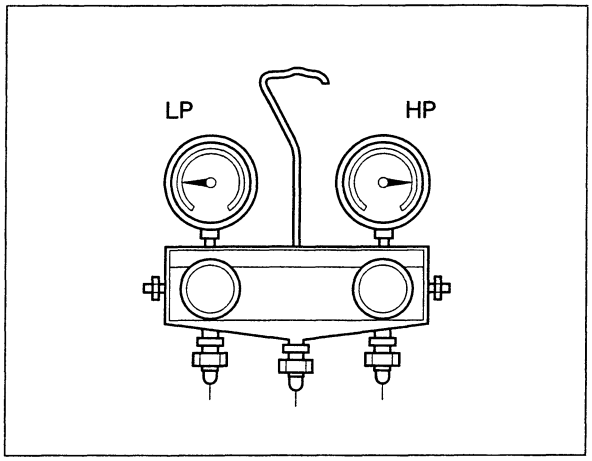
(1) Mount a low pressure gauge hose and a high pressure gauge hose on the check valve.
(2) Drive the air conditioner.
(3) Showing of higher LP side pressure and lower HP side pressure evidences ineffective compression.
Standard pressure
LP side pressure About 0.26MPa
HP side pressure About 1.42MPa



4.3.10 Air inclusion in ref.circuit

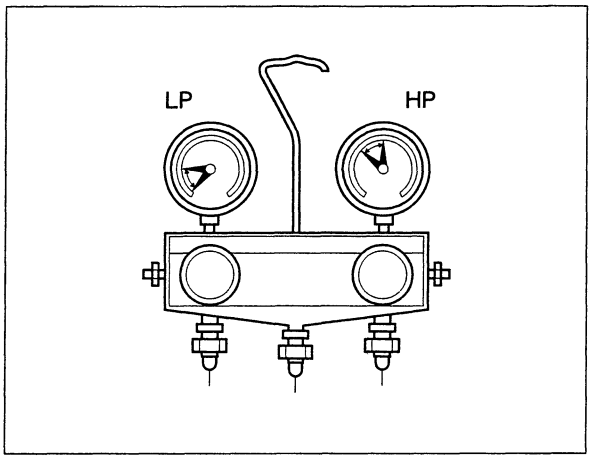
The abnormal reading of refrigerant circuit evidences afraid air inclusion.

A little higher LP side pressure. Noticeably higher HP side pressure.



4.3.11 Moisture inclusion in ref.circuit

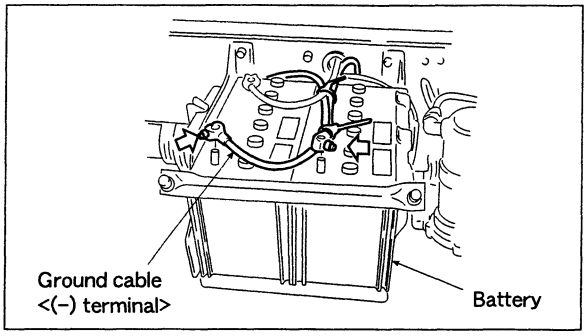
(1) During the operation, cooled air supply is interrupted periodically with a time interval.
This phenomenon evidences afraid water inclusion.
(2) Check the refrigerant pressure at a stop of the cooled air supply to make sure of the water inclusion.
LP side pressure ····Almost vacuum
HP side pressure ····Noticeably low



5. REMOVAL AND INSTALLATION

5.1 Precaution for removal and installation

(1) Disconnect the (-) ground cable from the battery, and place a cover on the battery.



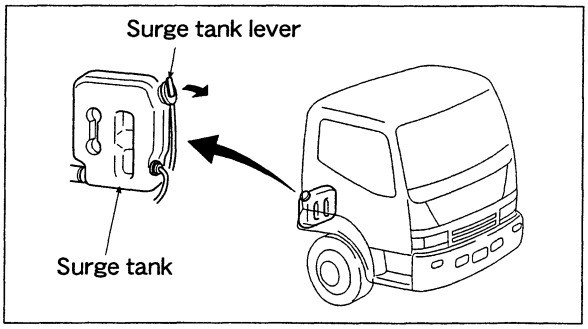
(2) Make certain all the openings are covered with caps in order to prevent entry of foreign substances such as dust and dirt.
(3) Never tamper with the brake and fuel systems, including the brake tubes and hoses.
(4) Avoid doing the work in a dusty place or outdoors in rainy weather. If tubes or functional parts are removed, put a cap in position immediately in order to prevent entry of dust and moisture.
(5) Connect the charging hose of the gauge manifold to the check valves (suction and discharge) of the suction hose and discharge hose, and recover the refrigerant by refrigerant recovery unit until its pressure is reduced to 0 kPa.
(Make sure that there is no internal pressure in the equipment.)
About discharging might result in the discharge of the refrigerant oil from the compressor.
(6) When coupling the flared tube, coat the flared portion with the compressor oil at the inner side.
(7) Make sure to use the wheel chocks.

5.2 Removal

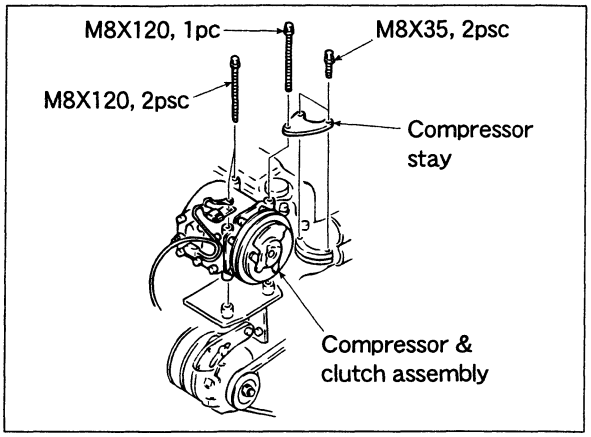
5.2.1 Inside engine room

(1) Compressor & clutch assembly

6D34

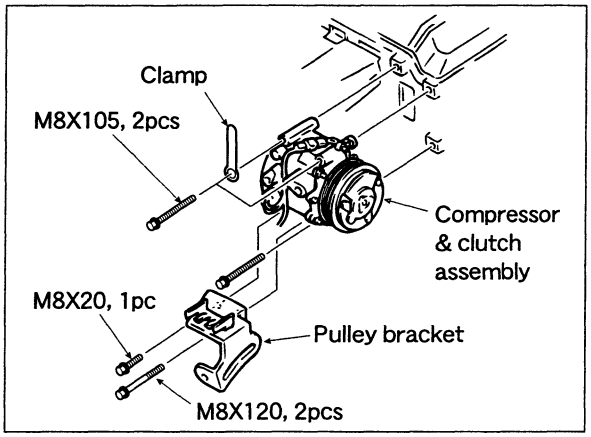


(a) Erect the pressure reducing lever of the radiator coolant surge tank cap to relieve the pressure from inside the radiator.
(b) Withdraw the wiring of magnetic clutch at the compressor.
(c) Remove the V belt by loosening fixture of the tension pulley.
(d) Take off the fixing bolts and anchor bolt : M8X35, 2pcs and M8X120, 1pc.
(e) Dismount the compressor stay.
(f) Take off the anchor bolts : M8X120, 2pcs.
(g) Dismount the compressor & clutch assembly.

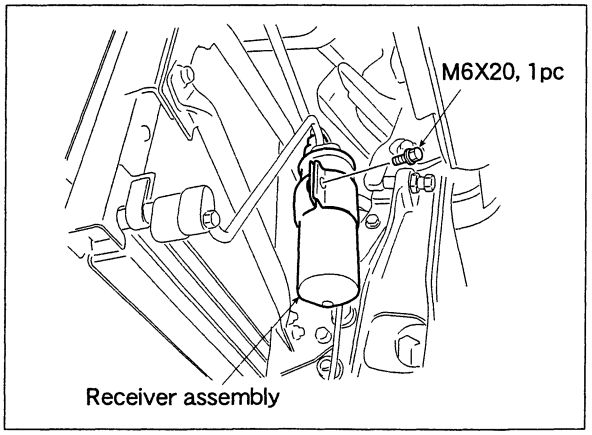


4M50T

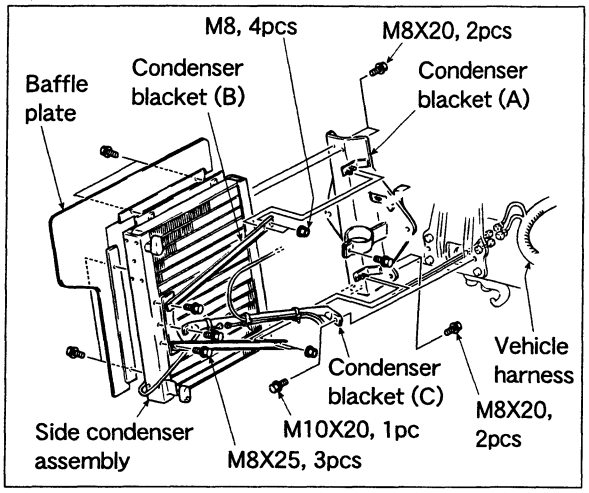
(a) Withdraw the wiring of the magnetic clutch at the connector.
(b) Remove the V belt by loosening fixature of the tension pulley
(c) Take off the fixing bolts : M8X105, 2pcs and M8X 120, 2pcs. (with clamp) and M8X20, 1pc.
(d) Dismount the compressor.



(2) Reciever assembly
(a) Unplug the dual pressure switch at the connector.
(b) Separete the interconnecting refrigerant pipe of the receiver assembly.
(c) Take off the fixing bolt : M6X20, 1pc.
(d) Dismount the receiver assembly.

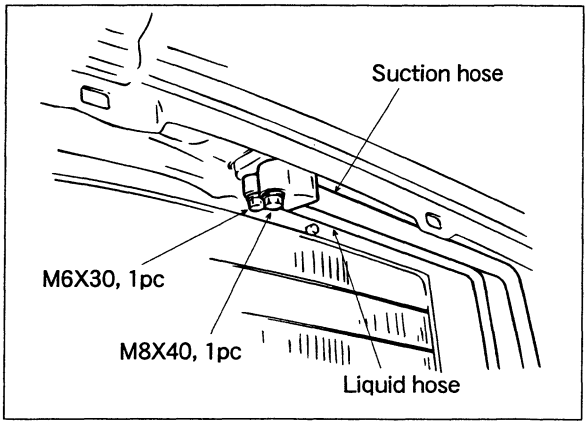


(3) Side condenser assembly
(a) Unplug the condenser fan harness at the vehicle side harness.
(b) Take off the fixing bolt : M8X25, 3pcs and M10X20, 1pc.
(c) Take off the fixing nut : M8, 4pcs.
(d) Dismount the condenser blacket (A), (B), (C).
(e) Take off the fixing bolt : M8X20, 4pcs.
(d) Dismount the side condenser assembly (and baffle plate).

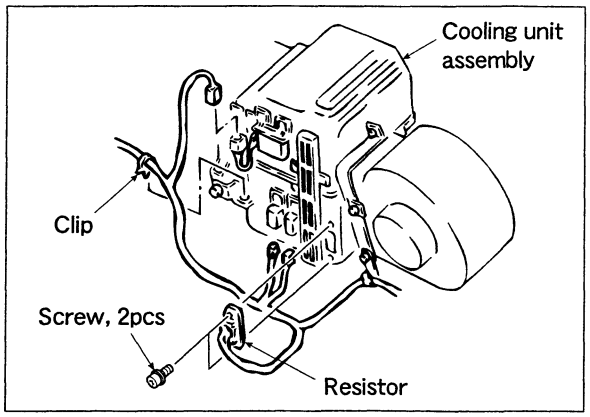


5.2 Cabin room

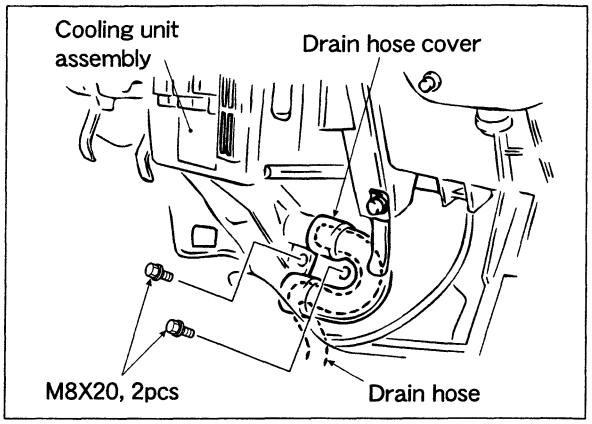
(1) Cooling unit assembly
(a) Separate the interconnecting refrigerant pipes of the cooling unit assembly.



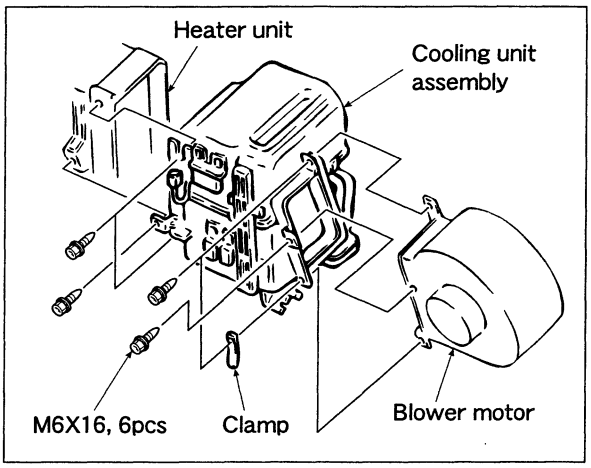
(b) Withdraw the wiring of the cooling unit assembly at the connectors.



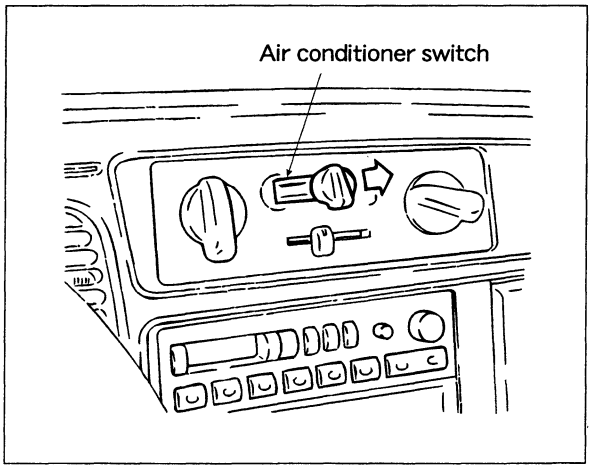
(c) Take off the fixing bolt : M8X20, 2pcs.
(d) Dismount the drain hose cover.
(e) Reconnect the drain hose from the cooling unit assembly.



(f) Take off the fixing screws : M6X16, 6pcs.
(g) Dismount the cooling unit assembly.



(2) Air conditioner switch
Pull out the air conditioner switch.



5.3 Installation

Installation is performed in the opposite sequence of removal.

M14	1.5	72~82	115~134	125~173

NOTE

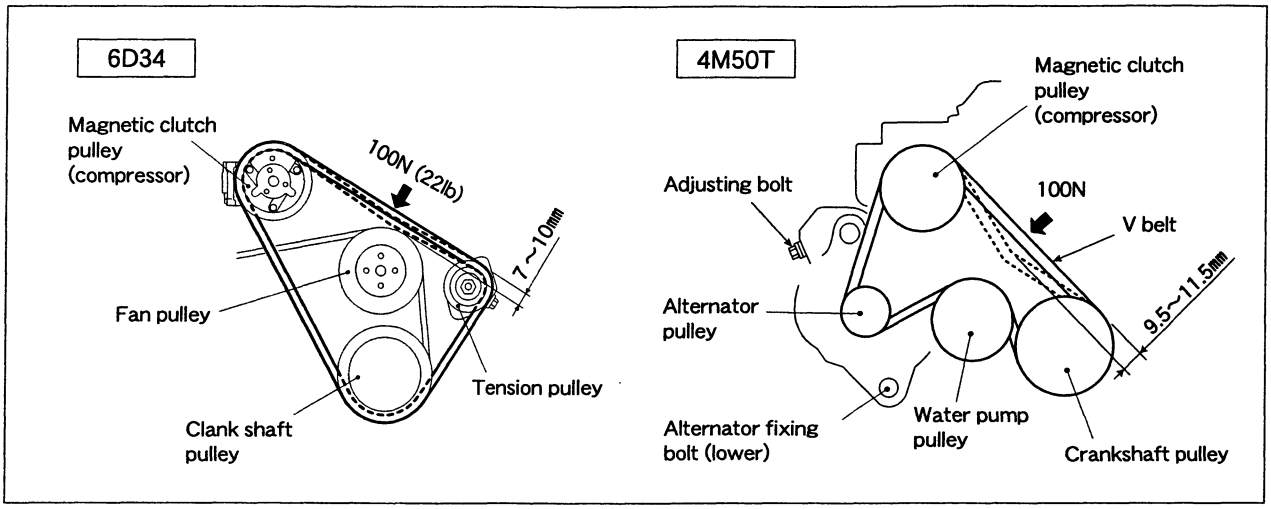
For the cases of spring washer seated, and thread or seating surface coated with oil, the value shall be reduced down to 85 percent of the data listed.

6. TREATMENT AFTER INSTALLATION

6.1 Check and adjustment

After installation, check the following points and confirm that everything is normal, then charge the gas, and do the performance and operation tests.

(1) Check if any abnormal vehicle performance, happens or not by installing the air conditioner.
(2) Check the operation of the magnetic clutch. (with the compressor disengaged)
(3) Check if any parts left unmounted or any tool left in the vehicle.
(4) Check to ensure that the temperature control lever operates properly.
(5) Check the tension of the belt.



6.2 Leak test

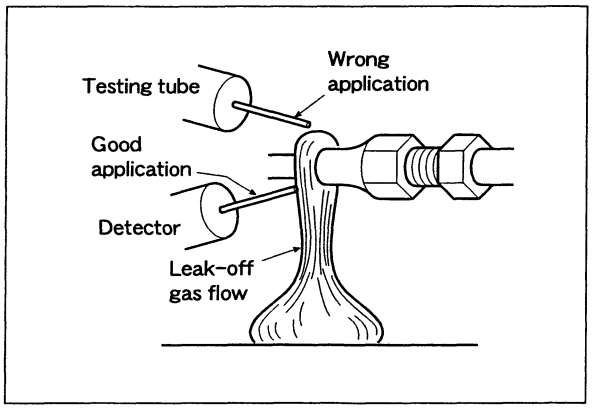
After all the piping works are completed, conduct an leak test by the following procedure to check any leaks at the flare coupling, etc. and then evacuate the system. If this leak test is omited and evacuation is immediately started, there is no way of detecting possible leak. If there are leaks, the specified vacuum cannot be attained. In order to save the service time be sure to conduct the leak test before evacuation.

6.2.1 Test point

(1) All pipe joint.
(2) Shaft seal and check valve on the compressor.

6.2.2 Test procedure

(1) For the gas leak test, the use of an electric gas leak detector is recommended. (HFC-134a SAE Approved)
(2) Perform the test at a place as in free from air flowing.
(3) The refrigerant is heavier than air. Leaks will concentrate at the bottom. Make certain that the testing tube is applied below the check point.



(4) The test should be performed patiently. Make certain that testing tube is moved slowly [approx. 10mm/sec].
(5) The high pressure side refrigerant circuit should be tested for gas leaks during operation. Those areas which are dangerous or hard to test during operation (including areas around the compressor and condenser) should be tested direct after shutdown.

(6) The low pressure side refrigerant circuit should be tested during shutdown after the gas pressure has balanced.
(7) The test should be performed on the basis of the following standards:

Gas leak test standards

test point / Instrument	Compressor shaft seal	Other parts
Electric gas leak detector	Pointer shall not swing more than 0.1mA at the low sensitivility.	Pointer shall not swing more than 0.1mA at the low sensitivility.
handle torch gas leak detector	Flame colour (moss green) shall not change.	

⚠ WARNING

- Smoking should be forbidden if a gas leak is detected.
- If a flame is applied to the refrigerant, toxic phosgene gas will be produced. Do not keep the detector in contact with a leaky point for a long time.

- Leak test procedure

1. Attach refrigerant supply and gauge set as shown with all valves closed. Open refrigerant supply valve on can.
2. Loosen the center charging hose fitting at the gauge manifold end to blow any air from the hose until it hisses for a few seconds, then refrigerant.
3. Open both gauge valves to partially charge the system and then close both valves.
4. The system can then be checked for leaks using an electronic leak detector.
5. If leaks are found that require the system to be opened (to repair or replace hoses, fittings, etc.), release any charge in the system.
6. After checking and repairing leaks, system must be evacuated.

6.3 System charging

GENERAL PRECAUTIONS

⚠ WARNING

When handling refrigerant (HFC-134a), the following precautions must be observed.

- Always wear eye protection and gloves while handling refrigerant.
- Be careful that liquid refrigerant does not contact the skin.
  If liquid refrigerant strikes eye or skin:
  - Do not rub on skin.
  - Splash large quantities of cool water on the eye or skin.
  - Flush eyes or skin with cool water for 5 minutes.
  - Rush to a physician or hospital for immediate professional treatment.
  - Do not attempt to treat it yourself.
- Keep the refrigerant (HFC-134a) container below 40℃.
- Do not handle the refrigerant in an enclosed area having an open flame; the refrigerant may produce a poisonous gas.
- Use approved recovery equipment to recover HFC-134a refrigerant before attempting service of this or any other HFC-134a system.
- Do not attempt to leak test an HFC-134a system with high pressure air or nitrogen. Mixing HFC-134a with a concentrated quantity of air may be combustible in the presence of ignition.

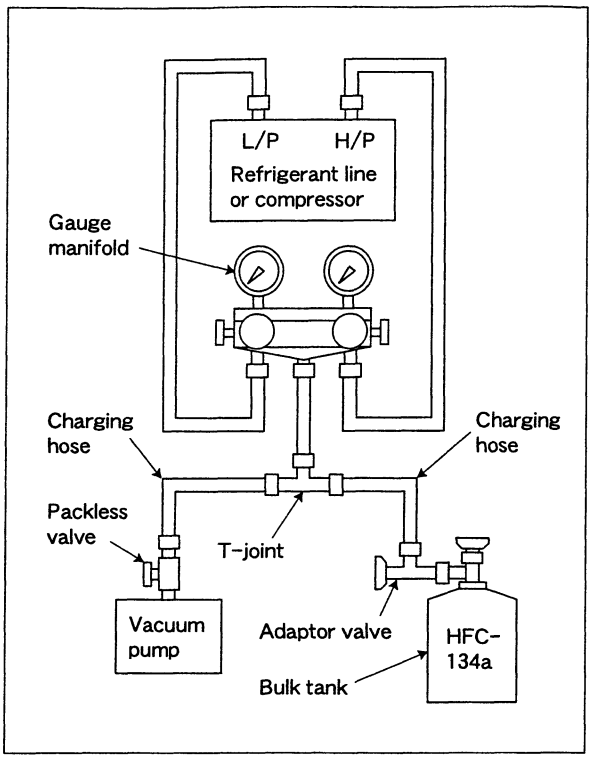
6.3.1 Evacuation

INSTALLATION OF CHARGE EQUIPMENT

(1) Connect the gauge manifold to the service valves.
(2) Connect the packless valve to the vacuum pump.
(3) With the charge valve handle turned back all the way, install the bulk tank.
(4) Connect each charge equipment as illustrated.

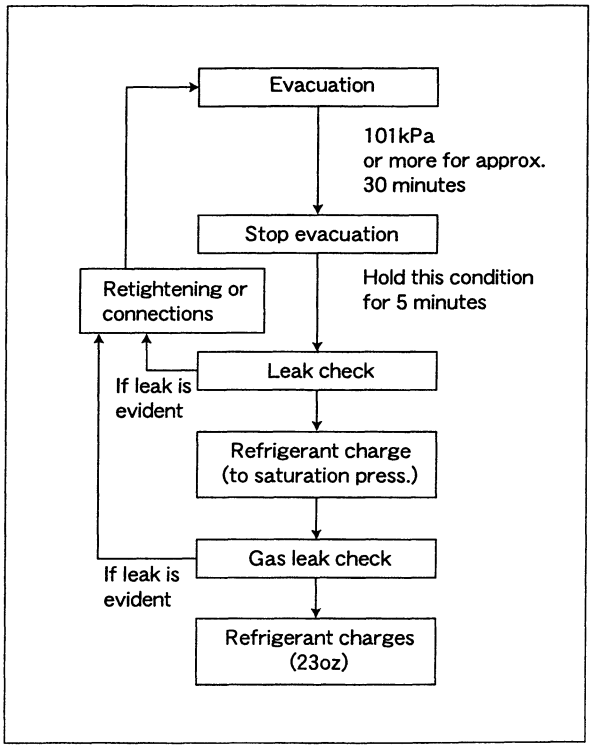
⚠ CAUTION

1. Do not connect the high and low pressure sides adversely. (Connect high pressure side to the condenser and low pressure side to the cooling unit.)
2. The indications "DIS" and "SUC" on the compressor indicate high and low pressure sides respectively.



6.3.2 Evacuate the system

The refrigerant system must have been evacuated using the previous procedure before charging. Charge using only HFC-134a refrigerant. HFC-134a is available in bulk tank. Follow the safety precautions for handling HFC-134a as listed in this section.
Follow the evacuation procedure below and at right.
This procedure assumes no HFC-134a refrigerant has been introduced into the system. If evacuating a charged system, it is necessary to recover the existing HFC-134a refrigerant before continuing with these instructions.
Refer to the recover equipment manufacture's instructions for proper refrigerant recovery.



CHARGING WITH BULK TANK

When using disposable cans of this type, follow carefully the tank manufactures instructions.

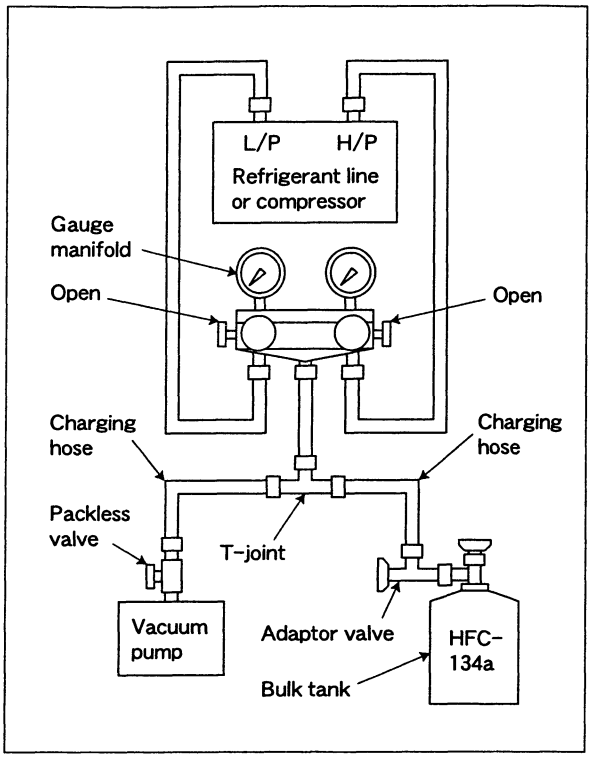
(1) Start up the vacuum pump.

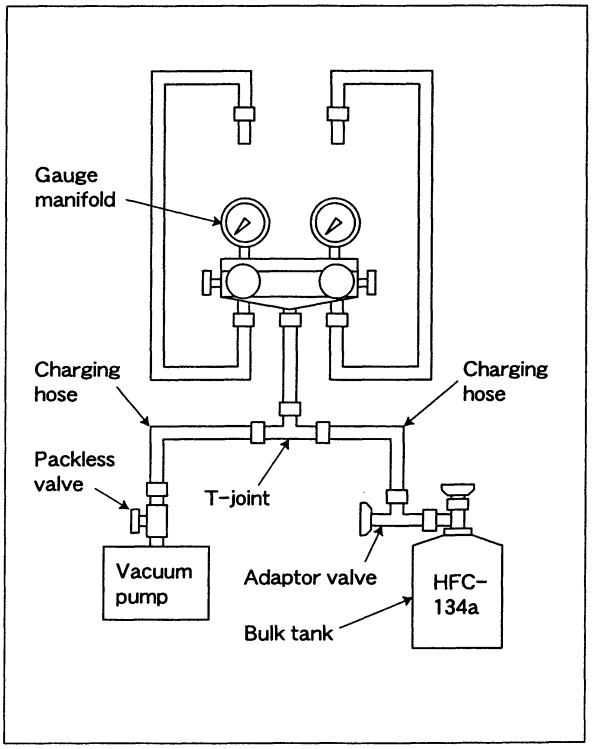
> ⚠ CAUTION
>
> 1. Do not use the compressor for evacuation.
> 2. Do not operate the compressor in the vacuum condition; damage may occur.

(2) Open the gauge manifold handles and the packless valve.
(3) Evacuate to a vacuum reading of 101kPa higher (approx.30 minutes).
(4) Turn back the packless valve all the way and close the bulk tank.
(5) Stop the vacuum pump and allow to stand for 5 minutes.
(6) Check for leak. (Good if the vacuum is held.)
(7) Tighten the charge valve handle to puncture the bulk tank.
(8) Open the charge valve to charge the system with refrigerant.
(9) When the refrigerant is no longer drawn in, turn back the high pressure side gauge manifold handles.
(10)Check for gas leaks using a leak detector.
(11)Start the engine.
(12)Operate the air conditioner and set at the lowest temperature (MAX. COOL).
(13)Fix the engine speed at 1500min^{-1}.
(14)Continue charging system until proper refrigerant quantity is introduced into the system.

> ⚠ CAUTION
>
> If the bulk tank is inverted, liquid refrigerant may be drawn into the compressor damaging it by liquid compression. Keep the bulk tank upright to ensure that refrigerant is charged in gas state.

(15)Upon completion of charging, turn back the low pressure side gauge manifold handles.





6.3.3 Removal of charge equipment

(1) Close the charge valve.
(2) Remove the gauge manifold from each service valves.

> ⚠ CAUTION
> Do not remove the bulk tank, T-joints and adaptor valves but keep them connected for next charge operation.

OPERATING LOW REFRIGERANT LEVEL

Locate the souce of the low refrigerant level, recover system, repair system, evacuate system, charge ststem, check for leaks.

> ⚠ CAUTION
> If the bulk tank is not emptied completely, keep the charge valve connected to the tank for next charging.

6.3.4 Discharging system

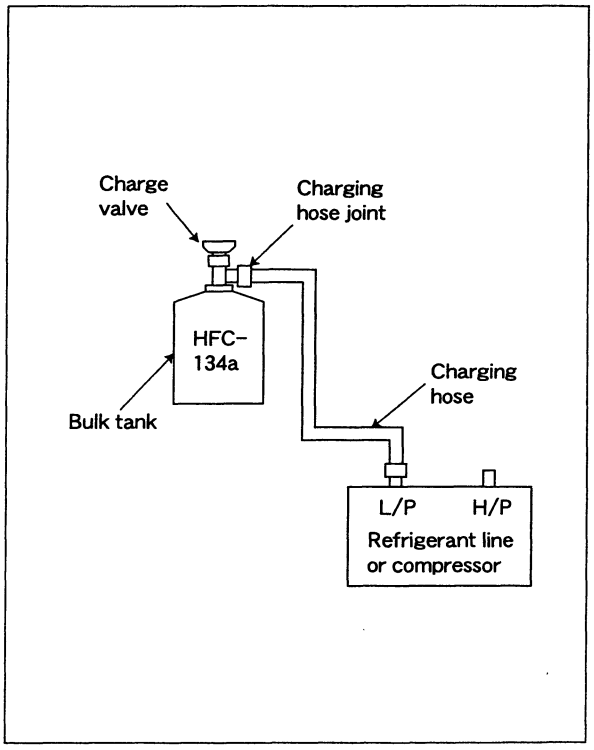
Use the refrigerant recovery unit which can be purchased in local market to discharge refrigerant gas from the system.

> ⚠ CAUTION
> Refer to that Refrigerant Recovery Unit Instruction Manual for operation which is attached on the unit.

LIQUID CHARGE, through high side using charging station:

> ⚠ CAUTION
> Do not run engine when performing liquid charge; compressor will be damage.

(1) After the system is evacuated, close gauge valves, connect center hose to refrigerant supply. Loosen center fitting at gauge to blow any air out of the hose and then retighten.
(2) Following charging station manufacture's instructions charge the system until 23oz of refrigerant is pumped into the system.
(3) When system is fully charged, close high gauge valve and refrigerant supply valve, then quickly disconnect gauge hoses from service
(4) After charging the system, refer to pre-delivery inspection.



6.4 Performance test

6.4.1 Preparation

Reinstall all vehicle parts that were removed for installation of the air conditioner at their original positions, adjust the mounting, and test the following items.

(1) Installation of grommets.

Install the specified grommets.

6.4.2 Stationary performance test

(1) Operating conditions

(a) Place the vehicle in the shade with doors open.

(b) Keep the return air temperature between 25 to 30℃, (Adjust by changing the opening degree of the doors).

(c) Set the fan switch to the max position.

(d) Turn the thermostat control lever to the cool position.

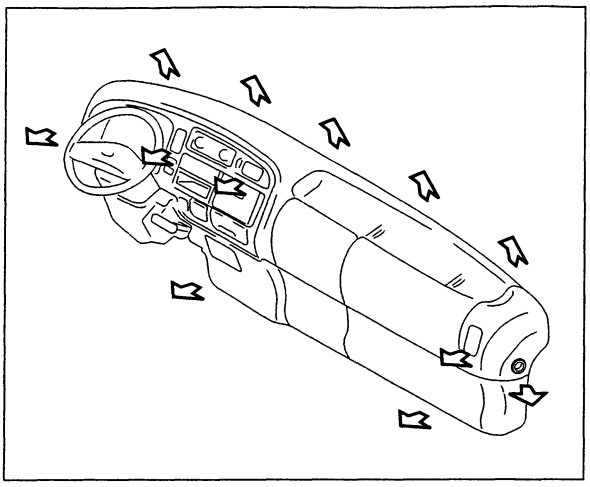
(e) Set the engine speed to approx. 1500min^{-1}.

(f) Set the high pressure at 1.17 to 1.37 MPa.

(If the high side pressure does not rise up, place paper or the like in front of the condenser.)

(2) Test procedure

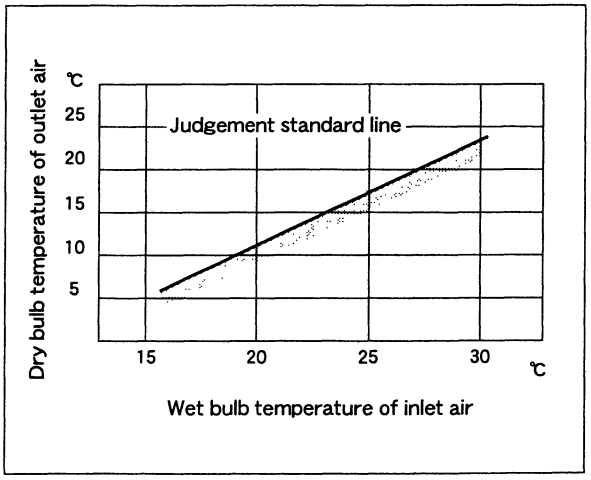
Operate the air conditioner for more than 10 minutes under the above operating conditions in order to stabilize the high and low pressures. Then perform the test by the following procedure:



(a) Measure the outlet air temperature at the inside space of the outlet grille.

(b) Measure the air conditioner intake air temperature, humidity, etc, and the items shown in the Table of Measuring Items at a position free from the effects of cool outlet air.

(c) The intersecting point of the plotted line perpendicular to the point which corresponds to the air conditioner intake and outlet air temperature difference and the plotted line perpendicular to the relative humidity of intake air should be between the oblique lines in figure.



7. MAINTENANCE

No.	Check point	Service and inspection intervals				
		When used only in summer (approx. for three months)		When used in all seasons		
		At the beginning or season	At the end of season	Every 5,000km (3,000miles)	Every 10,000km (6,000miles)	Every 20,000km (12,000miles)
1	Check condenser and radiator fin for clogging.	○	○	○		
2	Retighten all bolts.	○			○	
3	Check for refrigerant leaks.	○			○	
4	Check refrigerant level.	○		○		
5	Check V-belt tension.	○		○		
6	Check operation of magnetic clutch.	○			○	
7	Check operation of thermostat.	○				○
8	Cooling unit assembly performance test.	○		○		
9	Compressor overhaul.			Every four years		Every 40,000km (24,000miles)

⚠ WARNING

Even after the hot season is over, the air conditioner should be kept ready for operation all year round. Do not remove the V-belt or other parts.
This is because the air conditioner must be operated once a week for several minutes regardless of the season in order to prevent gas leaks caused by drying of the compressor shaft seal, and also to maintain the compressor itself in the best condition.

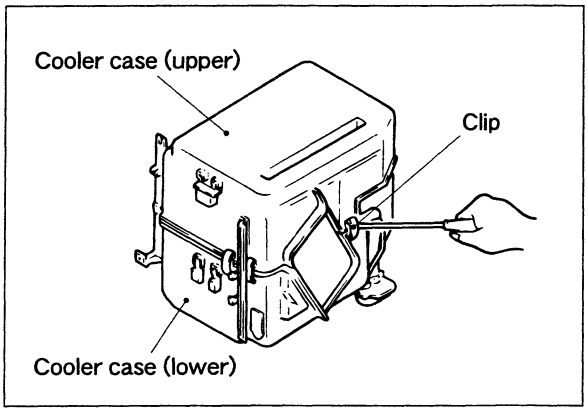
⑯ Baffle plate
⑰ Insulation rubber
⑱ Air filter

8.2 Cautions in disassembling

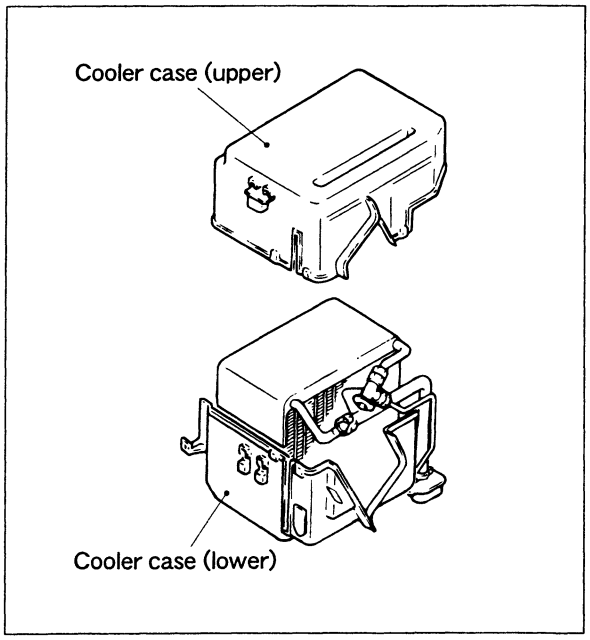
(1) Direct after disconnecting the refrigerant piping blind the opening to prevent dust and moisture etc. from eatering in it.
(2) When disconnecting the expansion valve, surely apply two spanners to prevent unstable twisting from applyng with the one for supporting and the other for torquing at the connection.
(3) Pipings in the cooling unit assembly should be handled gently. Particularly, the ingress and egress portions should be from any bending trouble in carrying it.
(4) If the cooling unit assembly is stored, or transported on disassembled condition, be careful not to deform the fins.
(5) When disconnecting the wiring, avoid pulling it with the insulation cover catched, but apply force by pinching the terminals or by catching the connectors.

8.3 Disassembling

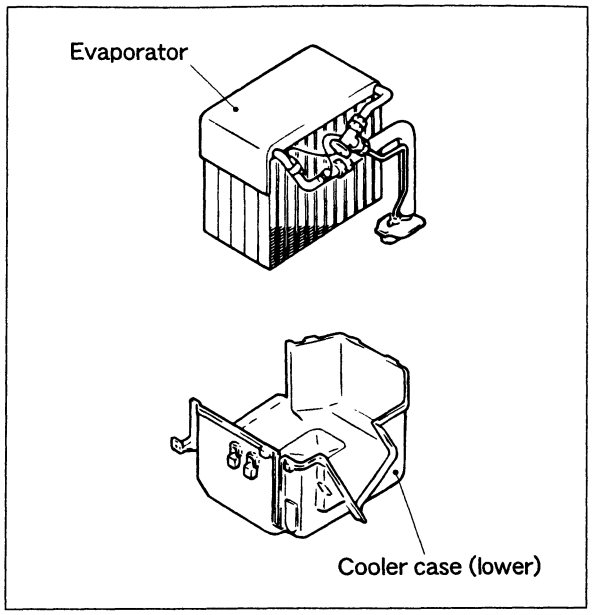
(1) Remove the clips for jointings the upper & lower side cooler case with a flat type screwdriver.



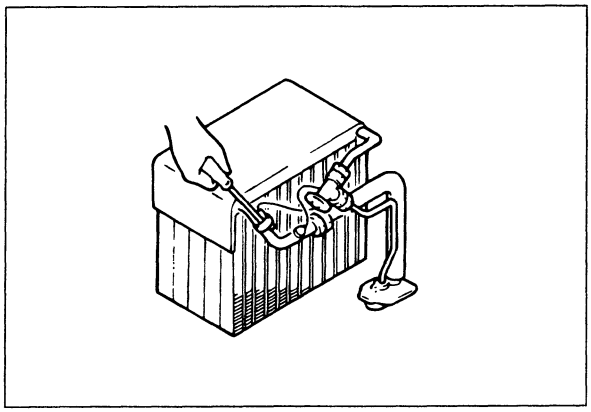
(2) Dismount the cooler case (upper).



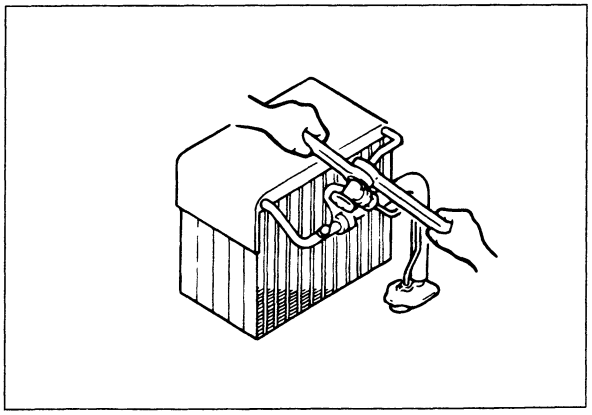
(3) Dismount the evaporator.



(4) Separate the expansion valve.
Dismount the feeler bulb at the suction side.

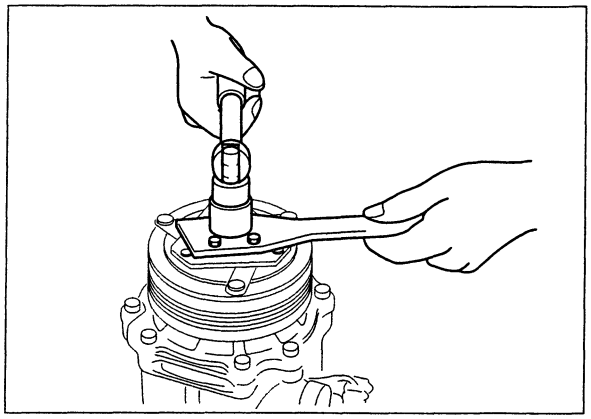


(5) Dismount the expansion valve from the circuit.

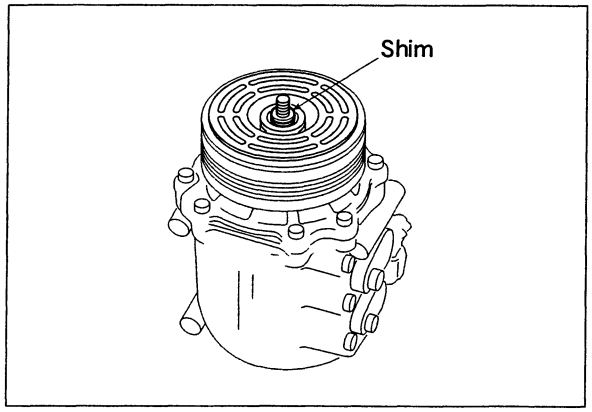


9. COMPRESSOR & CLUTCH ASSEMBLY

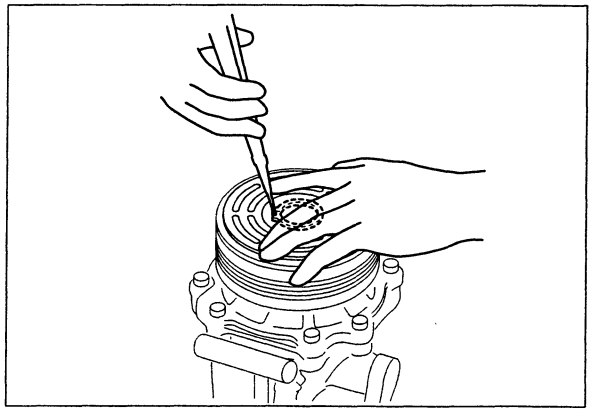
9.1 Disassembling the clutch



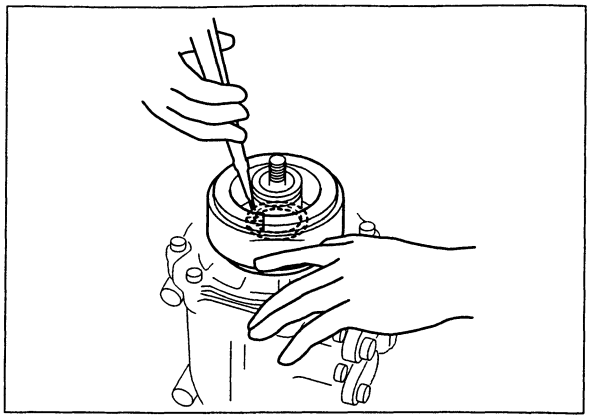
(1) Removal of armature plate.
  (a) Lock up the armature plate with a armature plate fixture and remove the lock nut.
  (b) Remove the armature plate.



(2) Remove the shim.



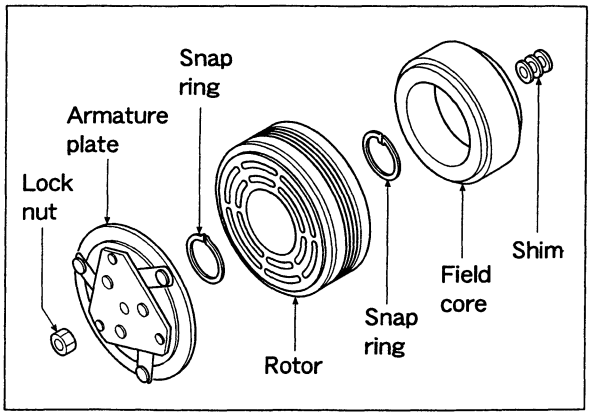
(3) Withdrawing rotor.
  (a) Remove the snap ring at the front case side with snap ring pliers.
  (b) Withdraw the rotor toward you and remove it from the front case.



(4) Removal of field core.
  (a) Remove the snap ring for fixing the field core with snap ring pliers.

  (b) Remove the ground wire with a cross point screwdriver and withdraw the field core toward you to remove it from the crank case.

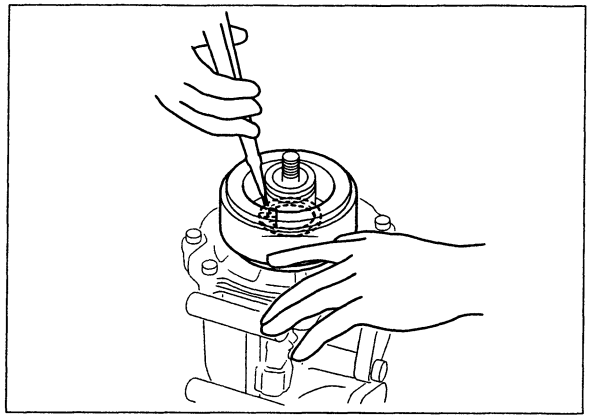
(5) Removal of key.
  Remove the key from the shaft using the top of a flat type screwdriver.



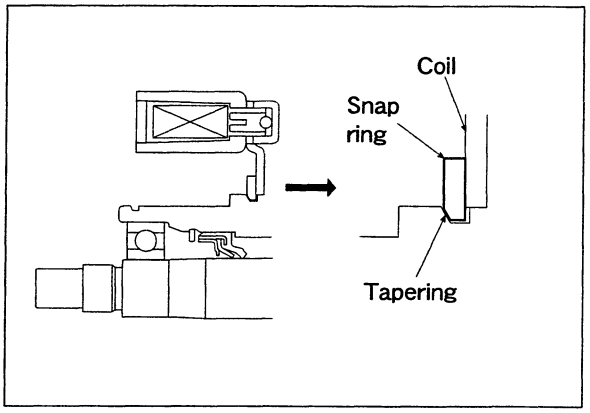
(6) Components of magnetic clutch.

9.2 Reassembly the clutch

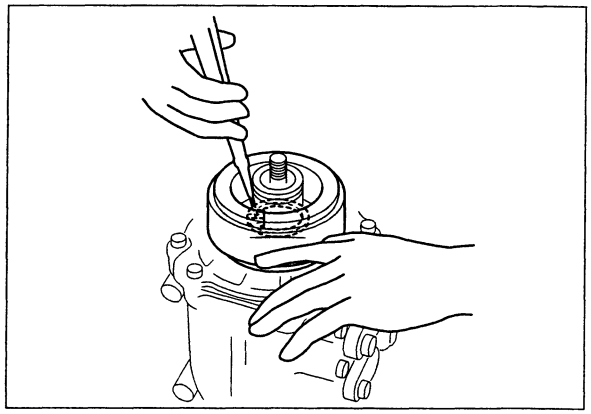
(1) Insert the key into the clankshaft.
(2) Insert the field core.



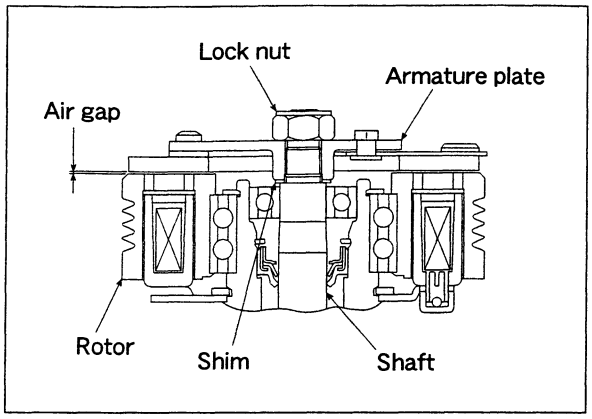
(a) Insert the field core into the front case and position it with a knock pin.
(b) Insert the snap ring for fixing field core into the groove and fix it with snap ring pliers as shown the below.



(c) Connect the ground wire.
(3) Insert the rotor into the front case.



(4) Insert the snap ring for the front case side into the groove with snap ring pliers.



(5) Insert the armature plate.
(a) Place a shim on the end of the shaft and insert the armature plate, adjusting to the key.
(b) Tighten the center bolt to the specified torque, 15.7N.m, with in between plain washer.
(c) Measure the air gap.
The air gap should be within 0.4 to 0.65 ㎜.
Adjust it by shim if it is not within the specifications.
Adjusting shim : 0.1, 0.3, 0.5, or 0.8 ㎜.

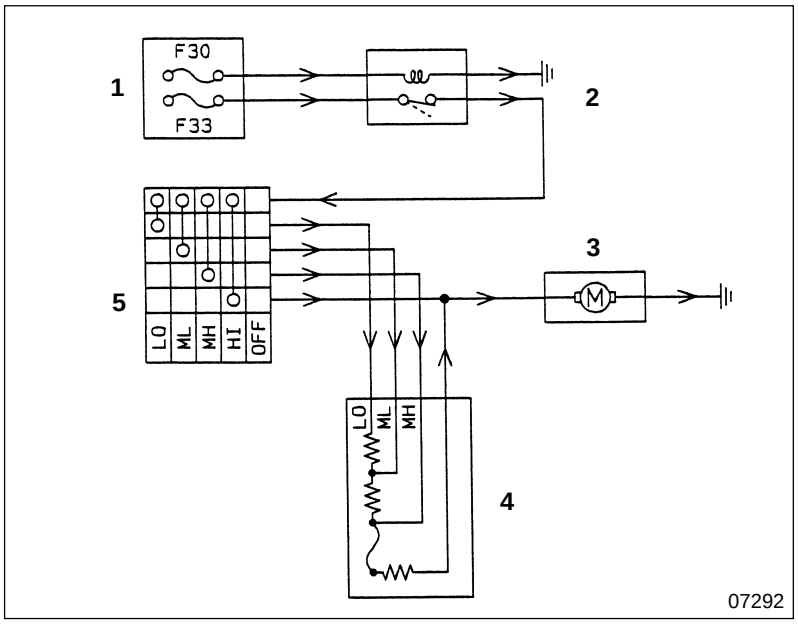
Outside air (Intake)

Inside air (Circulation)

Filtered air

- Warm engine coolant that has absorbed heat from engine **9** does not flow through thermostat **8** but circulates as follows:
  7→**2**→**10**→**9**
- Air sent to heater unit **1** from blower assembly **3** is warmed by heater core **2** (heat exchanger). Then the ducts deliver the warmed air to the cab.

Heater Electric Circuit



1 Fuse box
2 Blower fan relay
3 Blower motor
4 Blower resistor
5 Fan switch (Heater switch)

- The resistance of blower resistor **4** controls blower motor **3**, which in turn controls the air flow, except when the air flow is set to HI (high speed). When the air flow is set to HI, the current does not flow through the blower resistor.

Fan switch 5 set to LO position

- **1** (F30)→**2** (coil)→Ground
- **1** (F33)→**2** (contact point)→**5** (LO)→**4** (LO)→**3**→Ground

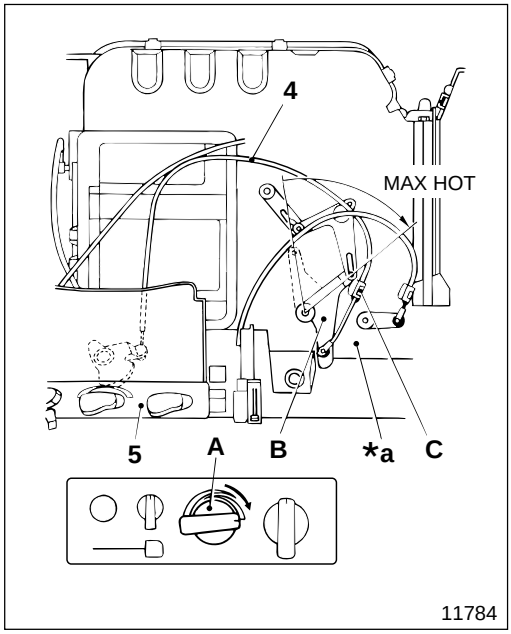
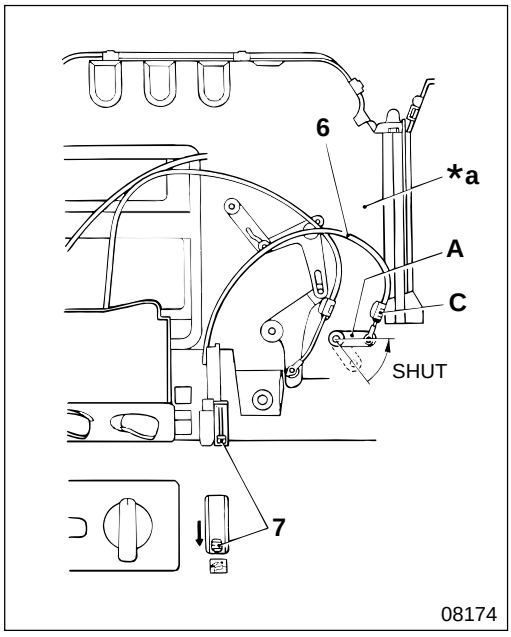
- Set inside/outside changeover lever **A** of heater control assembly **5** to (RECIRC : Inside air).
- Turn inside/outside air changeover damper lever **B** of blower assembly ***b** to RECIRC.
- Under these conditions, install inside/outside air changeover control cable **3** onto inside/outside air changeover damper lever **B** and fasten it with clip **C**.



4 Installation of air mixing control cable

- Fully turn temperature control dial **A** of heater control assembly **5** clockwise to MAX HOT (maximum heating).
- Turn air mixing damper lever **B** of heater unit assembly ***a** to MAX HOT (maximum heating).
- Under these conditions, install air mixing control cable **4** onto air mixing damper lever **B** and fasten it with clip **C**.



6 Installation of air bypass changeover control cable

- Set air bypass changeover control lever **7** to SHUT.
- Set air bypass lever **A** of heater unit assembly ***a** to SHUT.
- Under these conditions, install air bypass changeover control cable **6** onto air bypass lever **7** and fasten it with clip **C**.

FOREWORD

This Service Manual contains maintenance and repair methods for the Mitsubishi Fuso Truck FH Series. Read this manual carefully as an aid in providing correct, efficient maintenance. Please note that the information and specifications contained within this manual may change without notice. This is due to product modifications and contined vehicle improvements that are made throughout the model years. Should you encounter any discrepancy in the information provided, please do not hesitate to contact your nearest Mitsubishi Fuso Dealer or Mitsubishi Fuso Truck of America, Inc.

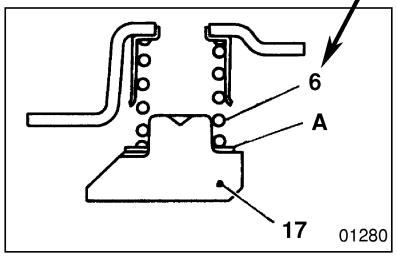
⑥ Service procedure

1

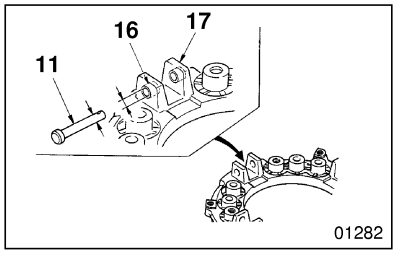
NOTE
Number(s) is this column match the key number(s) exploded view ①.

NOTE
The service procedure gives instructions in order of key numbers.



6 **Installation of pressure spring**
If the pressure plate **17** has been reqround, insert between the pressure plate and pressure spring **6** an adjusting washer **A** whose thickness matches that of the ground off material.

Regrind amount	Thickness and number of washer(s)
Less than 1 mm {0.039 in.}	Not required
1 mm {0.039 in.} (or more) to less than 2 mm {0.079 in.}	1.2 mm {0.047 in.}×1
2 mm {0.079 in.} (or more) to less than 3 mm {0.12 in.}	1.2 mm {0.047 in.}×2 or 2.3 mm {0.091 in.}×1



G L **Clearance between release lever pin and bushing**
If the measurement exceeds the specified limit, replace the defective part(s).

NOTE
Perform this check with the bushing 16 press-fitted into the pressure plate 17.

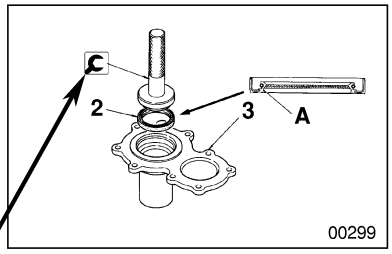
2

Service procedures contain a variety of symbols and other indications. Let's look at some examples.

23931

Key number

[Example 1: Special tools]



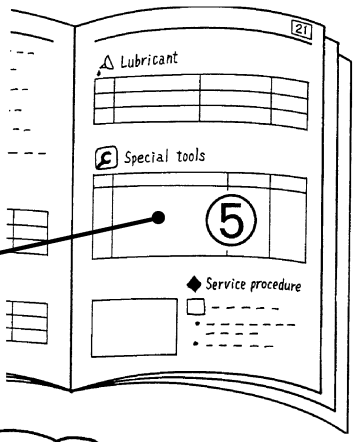
2 Installation of oil seal

- Apply grease to the lip **A** of the oil seal **2**.
- Using the Oil Seal Installer, fit the oil seal **2** into the front bearing retainer **3**. Make sure the oil seal is aligned as illustrated.

Name of special tool

Every special tool is indicated by a symbol. The text of the service procedure also includes the special tool's name. To see the part number and shape of a special tool, find the tool's key number and name in the "Special tools" table ⑤.

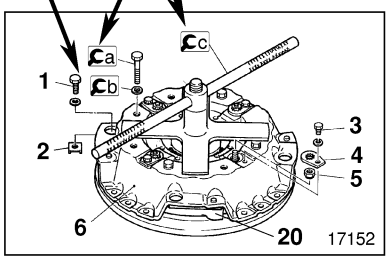
23932



26315

If more than one special tool is used, the symbols are supplemented by letters (for example, a, b and c) to enable cross-referencing between the exploded view and service procedure.

20277



6 Removal and installation of clutch cover

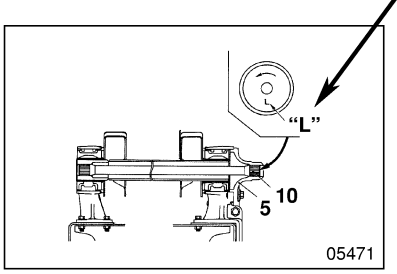
[Removal]

- Compress the pressure spring **8** using the c Clutch Installer, then remove the a Stopper Bolt, b Washer, strap bolt **1**, washer **2**, bolt **3**, lock plate **4** and support nut **5**.
- Gradually loosen the c Clutch Installer until the pressure spring **8** is ineffective, then remove the clutch cover **6**.

3

[Example 2: Identification or mating marks]

NOTE Any mark on an actual part is given in quotation marks “ ” in the service procedure.

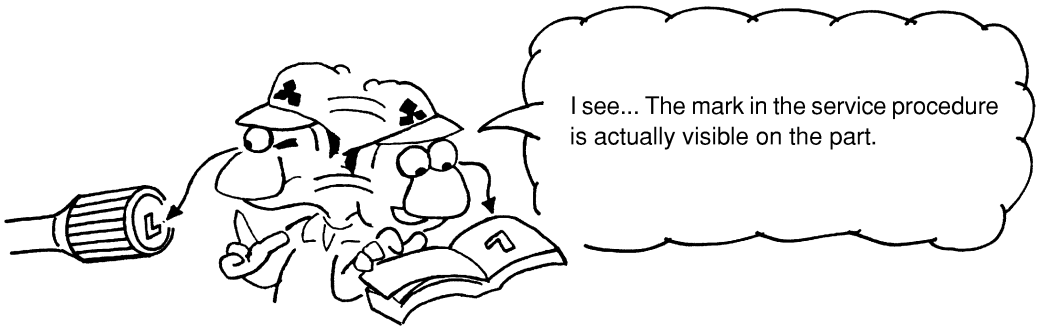


F Installation of torsion bar

Fit the torsion bar **10** such that the "**L**" identification mark is on the side of the anchor lever **5**.

CAUTION ⚠

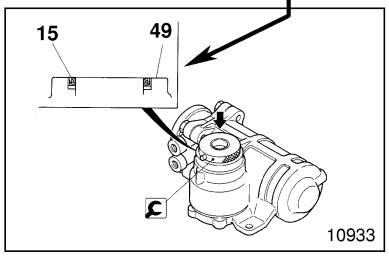
Make sure the torsion bar 10 aligned as specified. If the torsion bar is installed the wrong way around, the torsion direction will be reversed, resulting in damage.



4

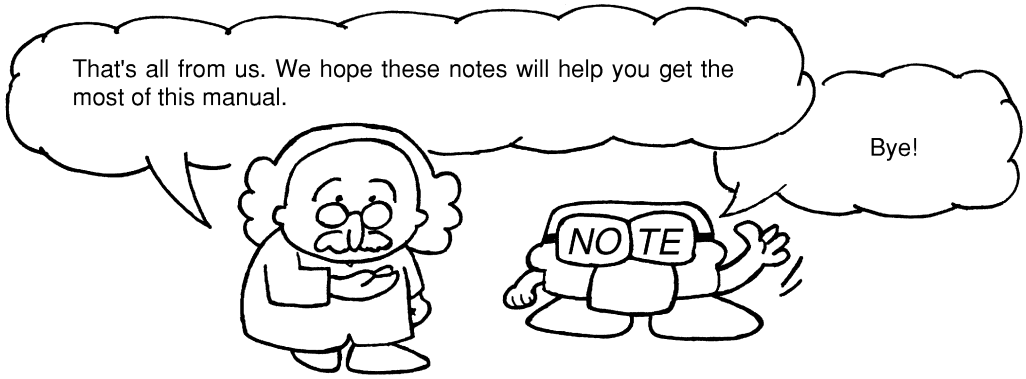
[Example 3 : Alignment of parts]

NOTE All illustrations show the correct alignment/direction of parts relative to each other. Provided the alignment/direction is shown clearly in the exploded view ①, no further explanation is given in the text of the service procedure.



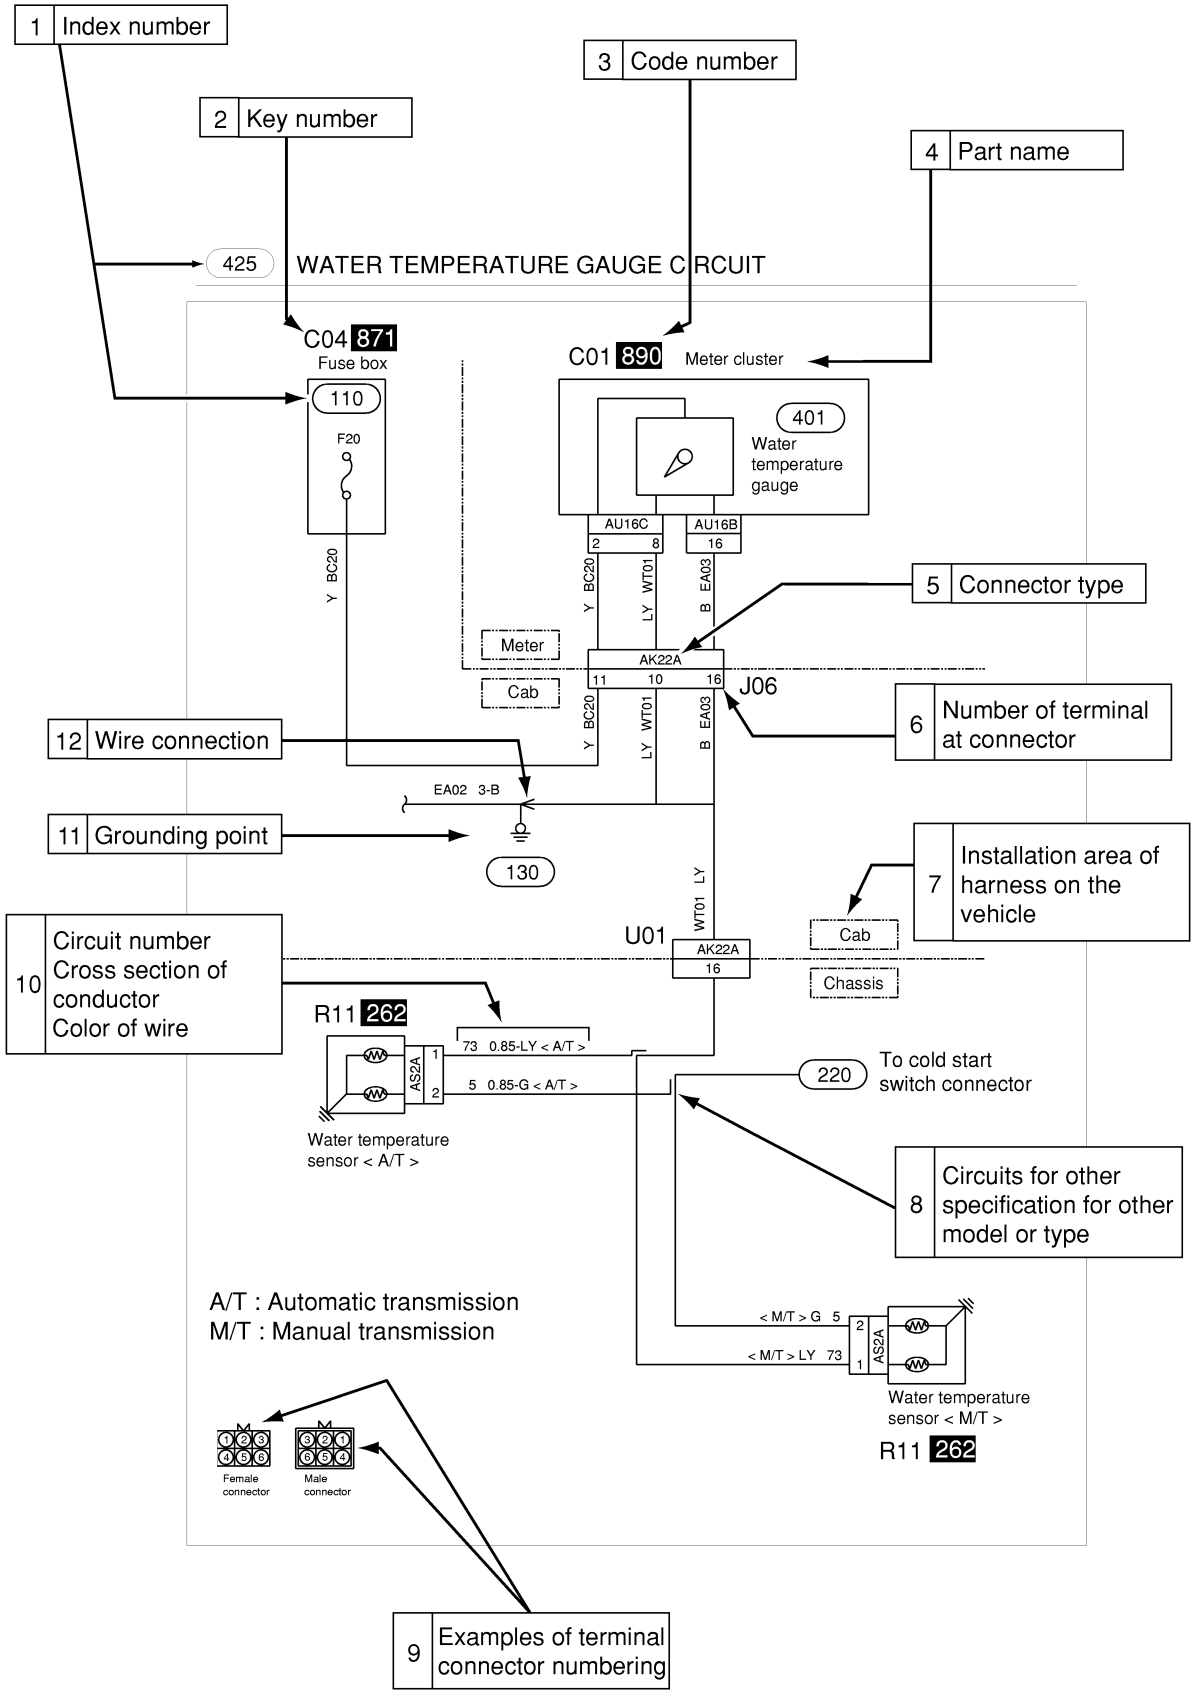
K Installation of oil seal

Fit the oil seal **15** into the body **49,** making sure it is aligned as illustrated.



HOW THIS MANUAL IS STRUCTURED

HOW TO READ CIRCUITS (GROUP 54)



Ⓟ45405

1 Index number: (110)

Each circuit has its own three digit Index number identified with three digits ((110)).

- How to read index number
  By proper using of the index number, it is possible to easily locate the circuit drawing in this manual as they are classified by function. (including "POWER CIRCUIT" (110) and "GROUND " (130) .)
- How to check the location of circuit drawing in each part
  The circuit drawing which can not be diagramed in one page due to its complicated structure (such as meter cluster and electronic control unit etc.), has its remarked index number to be connected to other circuit drawing. ((401) , (910) , etc.)

2 Key number: A01~

Key number is the number to indicate the installation position of the parts, and is shown by A01 ~ Z.
The details of the installation position are described in GROUP 10 .

3 Code number: **001** ~

Code number is the number to indicate an inspeciton procedure or detail exists and has three digits (**001**).
The details of the parts to be checked are described in GROUP 11 .

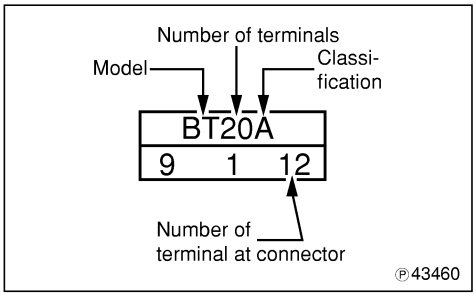
4 Part name

5 Connector type

Connectors are shown by □ without reference to Male or Female. In the box is a description of connector, number of terminals and its classification, etc.
Table of connectors is described in GROUP 00.

6 Number of terminal at connector

Terminal numbers of connector are shown by figures in the box.



7 Installation area of harness on the vehicle

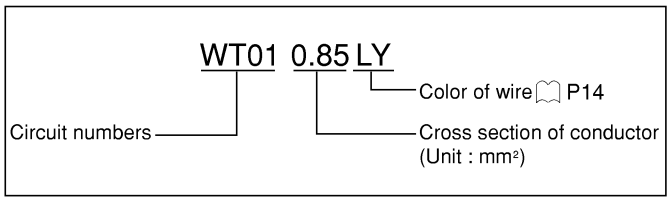
The location and boundary of the harnesses in the vehicle are shown in the each circuit drawing and it may help to check mounting position of connectors.

8 Circuits for other specification for other model or type

9 Examples of terminal connector numbering

As it is shown, for female connectors, with placing the lock upward then starting to put numbers from the upper left. And when it is male connector, put numbers from the upper right, also with placing the lock upward.

10 Circuit number, color of wire, and cross section of conductor are shown in circuit drawings.



Except for 0.5mm², Wire thickness is described in the circuit drawing. The reason why only wire thickness, 0.5 mm² is not described in the drawings is 0.5mm² is so common and so that the circuit drawing can be seen more easily.
(Examples) 0.5mm²: Y
0.85mm²: 0.85 — LY
3mm²: 3 — B

11 Grounding point

The actual locations of grounding points on the vehicle are shown. Refer to (130) for detailed information.

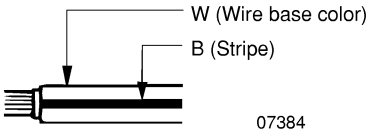
12 Wire connection

When the wires are connected into one point of the harnesses, the circuit drawing shows "Arrow mark".

CAUTION !
Be careful as the direction of the arrow does not show the direction of the electric current flow.

● Wire Colors

Example: WB means a wire whose base color is white and whose stripe is black.

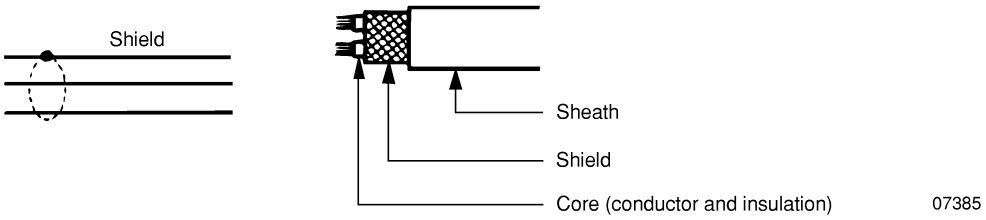


Wire base color		Wire base color + Stripe									
W	White	WR	White red	WB	White black	WL	White blue	WG	White green		
B	Black	BW	Black white	BY	Black yellow	BR	Black red				
R	Red	RW	Red white	RB	Red black	RY	Red yellow	RG	Red green	RL	Red blue
Y	Yellow	YR	Yellow red	YB	Yellow black	YG	Yellow green	YL	Yellow blue	YW	Yellow white
G	Green	GW	Green white	GR	Green red	GY	Green yellow	GB	Green black	GL	Green blue
Br	Brown	BrW	Brown white								
L	Blue	LW	Blue white	LR	Blue red	LY	Blue yellow	LB	Blue black	LO	Blue orange
Lg	Yellow green	LgR	Yellow green red	LgY	Yellow green yellow	LgB	Yellow green black	LgW	Yellow green white		
O	Orange										
P	Pink	PB	Pink black								

● Shield Wire

A shield wire is clearly identified as follows:

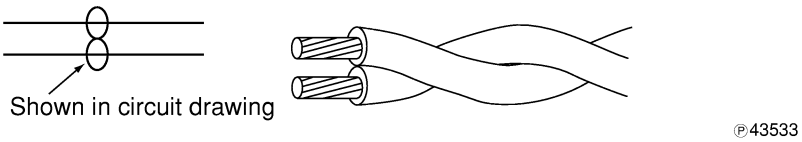
Example



● Twisted wire

Twisted wires are identified as follows:

Example:



TERMS

The terms in this manual are defined as follows.

● This service manual contains important precautionary instructions and supplementary information under the following four headings which identify the nature of the instructions and information:

DANGER⚠	Precautions that should be taken in handling potentially dangerous substances such as battery fluid and coolant additives.
WARNING⚠	Precautionary instructions, which, if not observed, could result in serious injury or death.
CAUTION⚠	Precautionary instructions, which, if not observed, could result in damage to or destruction of equipment or parts.
NOTE	Suggestions or supplementary information for more efficient use of equipment or a better understanding.

● **Front and rear**

The term “front” is the fan side and “rear” the flywheel side of the engine.

● **Left and right**

The terms “right” and “left” shall be used to indicate the side as viewed from the flywheel side of the engine.

● **Terms of service standards**

(1) Standard value

Standard value specifications indicate the design dimensions of individual new parts, the standard clearance between assembled parts, or a standard value for an assembled part, whichever applies.

The figure in [ ] is the basic diameter.

(2) Wear limit

When the value of a part exceeds this wear limit it is no longer serviceable with respect to performance and strength and must be replaced or repaired.

● **Tightening torque**

Appropriate fastener tightening torque has particular importance with respect to performance. Tightening torque is specified in locations where applicable.

Where there is no specified figure for tightening torque, follow the table covering standard tightening torques. (See Group 00).

When the item is to be tightened in a “wet” state, it is indicated in the remarks column. Where there is no indication, assume it is to be assembled dry, and tighten to specified torque.

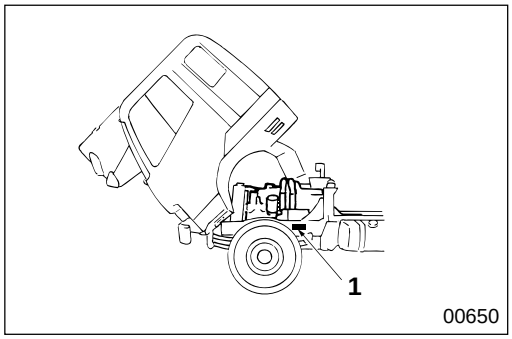
CHASSIS NUMBER AND ENGINE NUMBER/POWER TRAIN LABEL

CHASSIS NUMBER AND ENGINE NUMBER

The serial numbers for chassis and engines are assigned to the respective vehicles and engines in manufacturing sequence: each vehicle and engine has its own number. These numbers are required for registration and incidental inspection of the vehicle. Please do not fail to mention these numbers to the dealers when ordering spare parts.



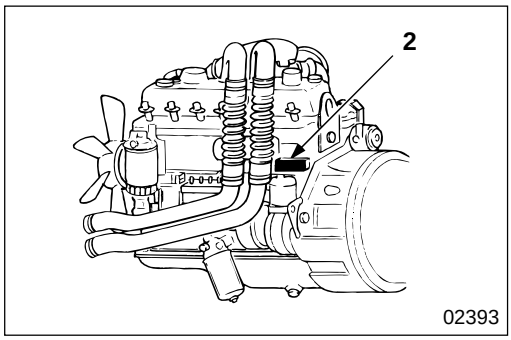
Chassis number

Chassis number **1** is punch-marked on the frame by the left-side front wheel.

Example : FK617H–□□□□□□

Vehicle model

Chassis number



Engine number

Engine number **2** is punch-marked on the left of the crankcase.

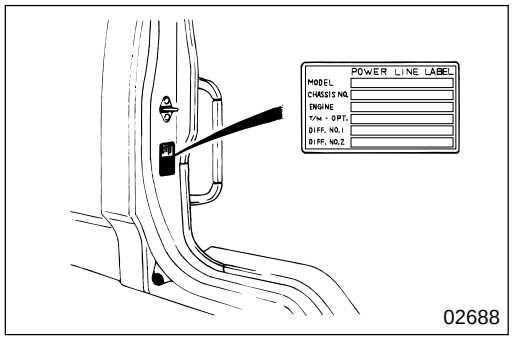
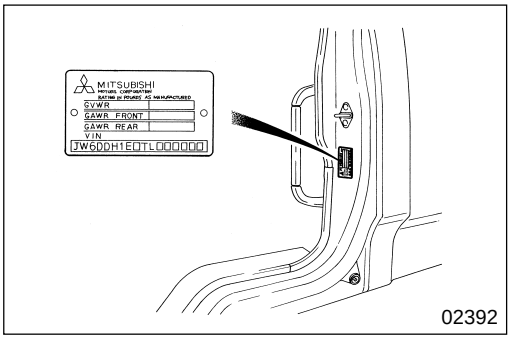
POWER TRAIN LABEL



Power train label **1** located in the position illustrated indicates the vehicle model, chassis number and information relevant to the vehicle's power transmission components.

VEHICLE IDENTIFICATION NUMBER



The vehicle identification number is punch-marked on the plate, which is attached in the position as illustrated.
The vehicle identification number consists of a 17-digit set of alphanumeric characters. Each digit represents the following specifications.

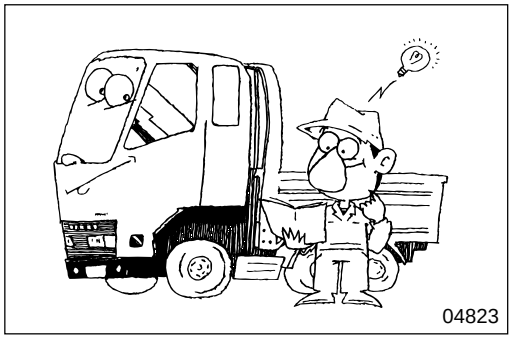
PRECAUTIONS FOR MAINTENANCE OPERATION

DANGER ⚠

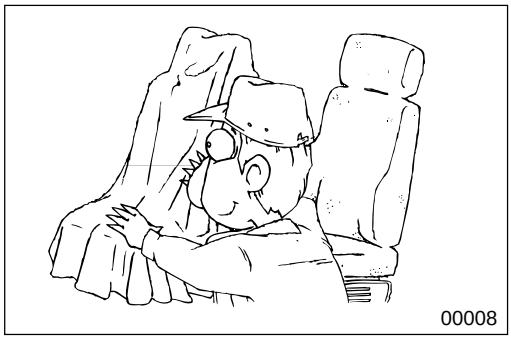
This product contains or emits chemicals known to the State of California to cause cancer and birth defects or other reproductive harm.

In order to determine the condition of the vehicle adequately, examine the vehicle beforehand to record the accumulated mileage, operating condition, customer's complaint, and other information that may be necessary. Prepare the steps to be taken and perform an efficient maintenance procedure.



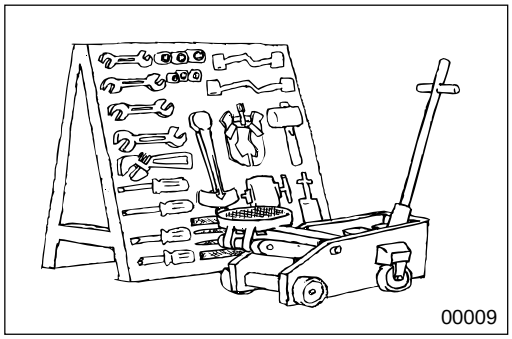
04823

Determine where the fault exists and check for the cause to see whether removal or disassembly of the part is necessary. Then follow the procedure specified by this manual.



00008

Perform maintenance work in a level area.
Prepare the following.
- To prevent the seats, upholstery, floor and bodywork from being spoiled or scratched, cover with workshop sheet cover(s).

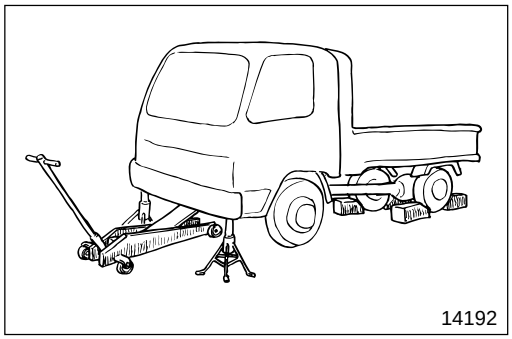


00009

- Prepare general and special tools necessary for the maintenance work.

WARNING ⚠

Do not attempt to use tools other than special tools where use of special tools is specified in this manual. This will avoid injury or damage.

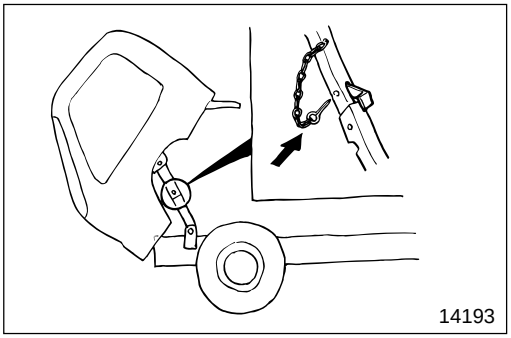


14192

When jacking up the vehicle to work under the vehicle, carry out the following preparatory work:
- Chock the wheels on both sides.
- Jack up the vehicle using an appropriately rated jack.
- Support the frame on jack stands.

WARNING ⚠

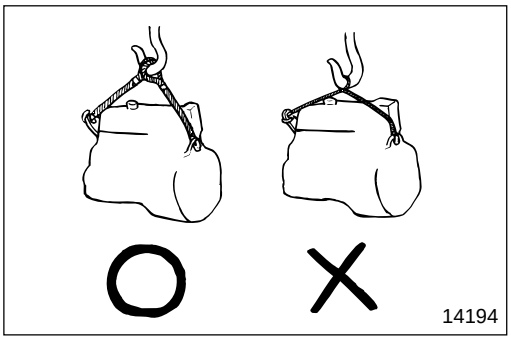
- **Chock the wheels securely so the vehicle does not move.**
- **Do not remove the chocks until the entire operation is completed.**
- **Supporting a vehicle on a garage jack only is extremely dangerous, so always support the frame on jack stands.**
- **Leave the garage jack and rigid racks in place until the entire operation is completed. Never remove them during the operation.**



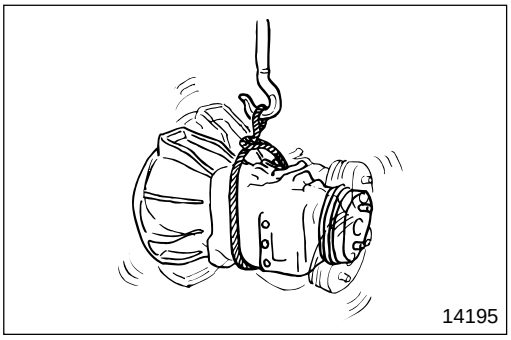
When tilting the cab, be sure to insert the safety pin into the cab stay so that the cab stay remains locked and cannot be released when the cab is tilted.

Pay special attention to safety when removing or installing heavy items such as engines, transmissions and axles.

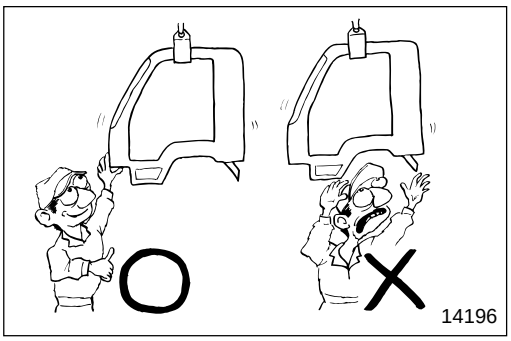
When lifting up heavy items using cables, pay special attention to the following points:



- Check the mass of the item to be lifted and use a cable capable of lifting that mass.



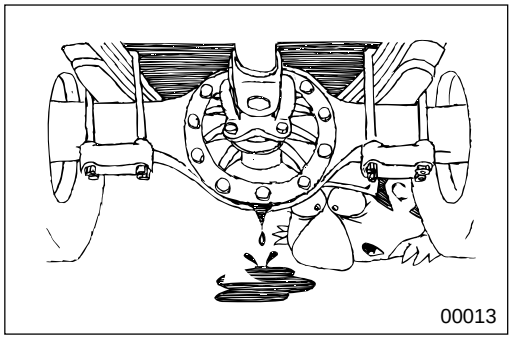
- If you do not have the specified lifting hanger, secure the item using cable taking the point-of-balance of the item into consideration.



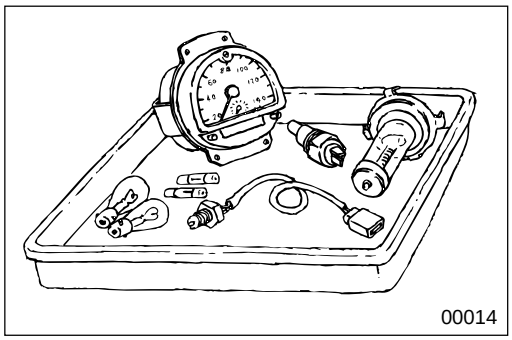
- You must work in a position where you will not be injured even if the cable comes undone and the lifted item falls.

PRECAUTIONS FOR MAINTENANCE OPERATION

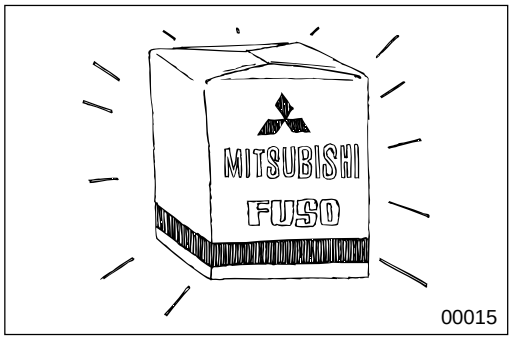
Be particularly careful not to work in shoes that have oily soles and are slippery. When working as a team of two or more, arrange signals in advance and keep confirming safety. Be careful not to accidentally bump switches or levers.



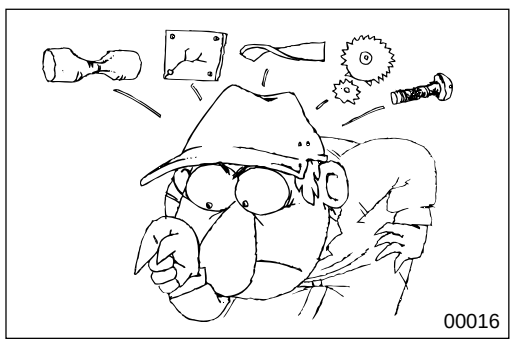
Check for oil leakage before cleaning the area having the fault otherwise you might miss detecting the leakage.



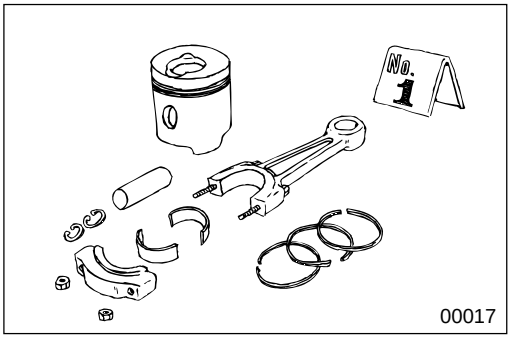
Prepare replacement part(s) beforehand.



Replace oil seals, packing, O-rings and other rubber parts; gaskets and split pins with new parts whenever any of them has been removed. Use only genuine MITSUBISHI replacement parts.



On disassembly, visually inspect all parts for wear and tear, cracks, damage, deformation, degradation, rust, corrosion, smoothness in rotation, fatigue, clogging and any other possible defect.

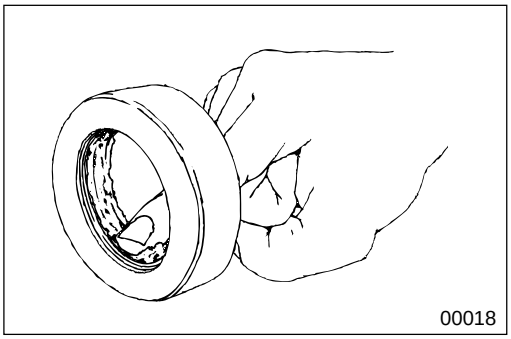


00017

Put alignment marks on part combinations before disassembly and arrange the disassembled parts neatly. This will help avoid mismating of the parts later.
Put the alignment marks, punch marks, etc. where performance and appearance will not be affected.
Cover the area left open after removal of parts to keep it free from dust.

CAUTION⚠

- **Take care to avoid mixing up numerous parts, similar parts, left and right, etc.**
- **Keep new parts for replacement and original (removed) parts separate.**

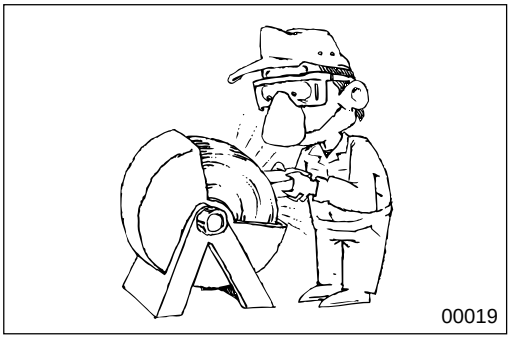


00018

Apply the specified oil or grease to U-packings, oil seals, dust seals and bearings during assembly.
Use only the specified oil, grease, etc. for lubricant, remove the excess immediately after application with a piece of waste, etc.

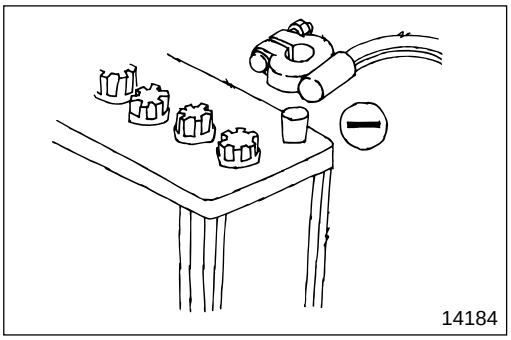
CAUTION⚠

When the specified lubricant, fluid and sealant is not available, you may use an equivalent.



00019

Wear goggles when using a grinder or welder. Pay full attention to safety by wearing gloves when necessary. Watch out for sharp edges, etc. that might injure your hands or fingers.



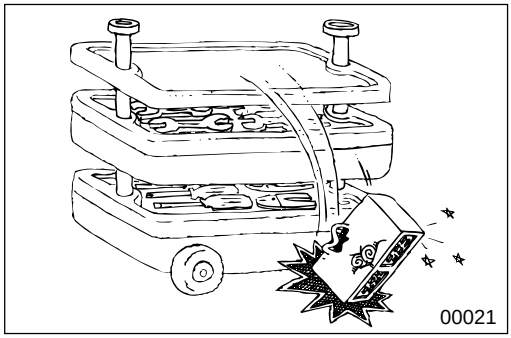
14184

Before carrying out maintenance work on the electric system, disconnect the negative terminals of the batteries to prevent them from short-circuiting and burning-out.

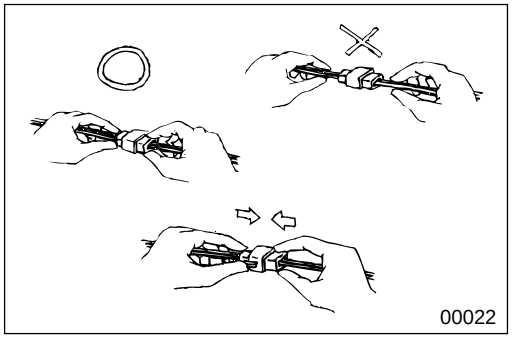
CAUTION⚠

Be sure to turn starter and lighting switches, etc. off before disconnecting or connecting battery terminals, because the semiconductors can be damaged.

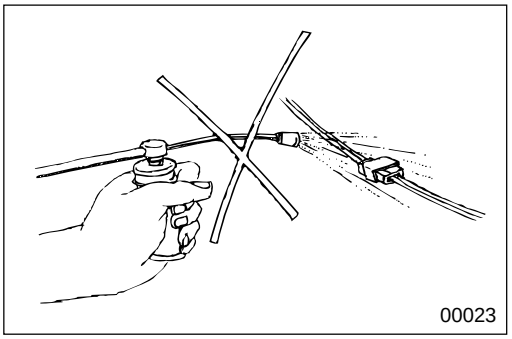
PRECAUTIONS FOR MAINTENANCE OPERATION



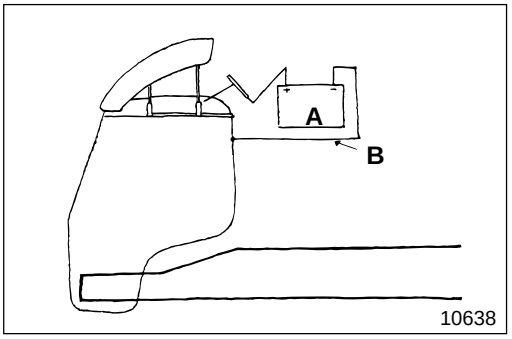
Take care when handling sensors, relays, etc. which are vulnerable to shock and heat. Do not attempt to remove the cover from, or apply paint to, the electronic control unit.



Pull the connector, and not the harness lead, to separate connectors. To separate a lock-type connector, first push toward arrow mark. To reconnect a lock-type connector, press the separated parts until they click together.



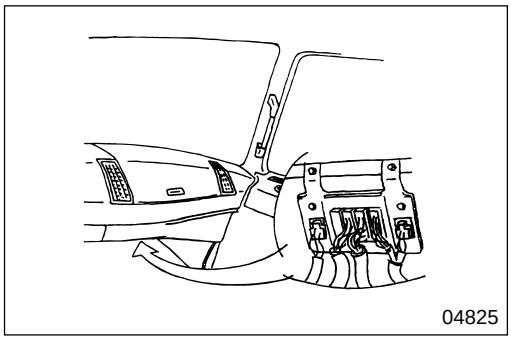
When washing the vehicle, cover the electric system parts and instruments with waterproof material beforehand (Cover with vinyl sheet or the like). Keep water away from harness wire connectors and sensors. If any of them should get wet, wipe them off immediately.



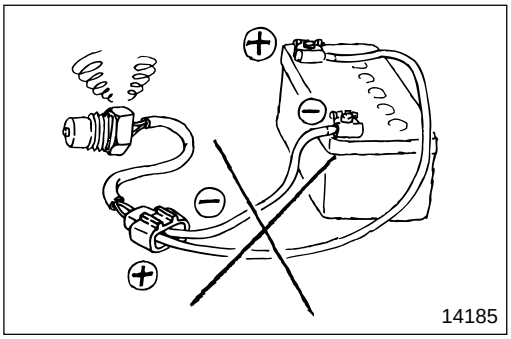
When using an electric welder, such electronic parts that are directly connected to the batteries might be damaged due to the flow of current from the welder that flows through the negative circuit. Parts that have switches might be subject to the same danger if the switches are left on. Therefore, do not fail to observe the following.

A : Welder

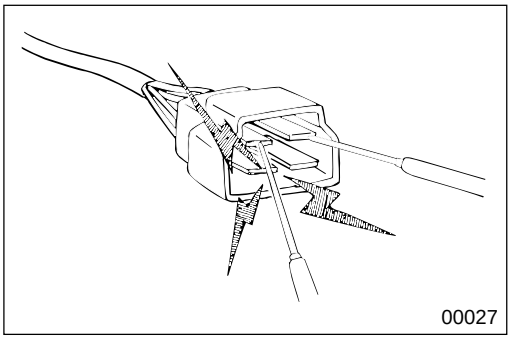
B : Connect the negative terminal of the welder as near as possible to the area that is to be welded.



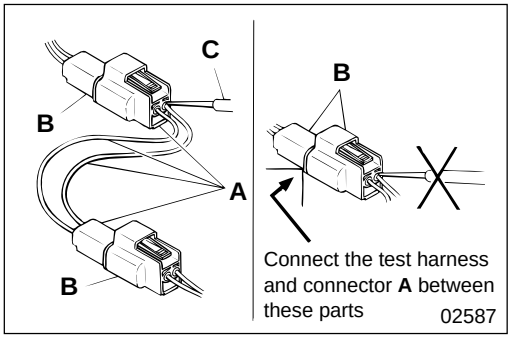
- Disconnect the negative terminals of batteries.
- Disconnect connections between the cab harness wires and the chassis harness wires.



To apply voltage for testing, check that the positive and negative cables are connected properly, then increase voltage gradually from 0 volt. Do not apply voltage higher than the specified value.
In particular, pay close attention to the electronic control unit and sensors, since they are not always fed the battery voltage.



When using testers or the like for continuity tests, be careful not to allow test probes to touch the wrong terminals.



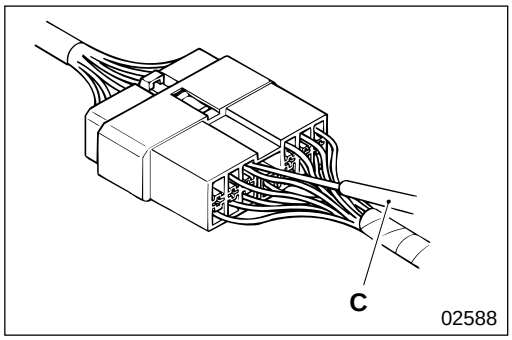
Measurement procedures using connectors

- **Test with connectors engaged (continuity through circuit obtained)**

  < Waterproof connector >

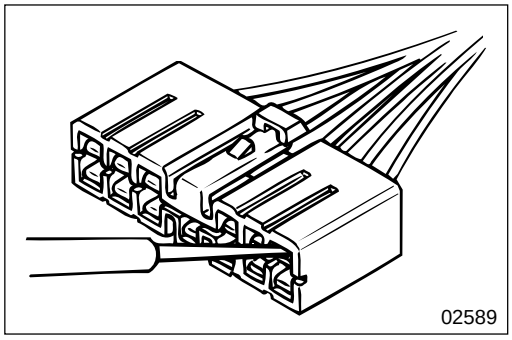
  Prepare a test harness and connectors **A**, then connect if between the two parts of harness **B** that is to be tested. Check the circuit by touching test probe **C** to the test connector.

  Never insert the test probe from the harness side of the waterproof connection, or waterproof performance might be diminished causing corrosion of the connector.



< Non-waterproof connector >

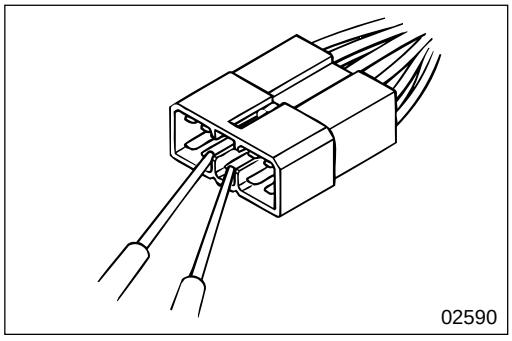
Insert test probe **C** from the harness side of the connector. Where control units, etc. have connectors that are too small to accept the test probe, do not force the test probe into them.



- **Test with connectors disengaged**

  Using female pins

  Insert a test probe into a terminal. However, do not force the probe into the terminal, or it will cause a poor contact.

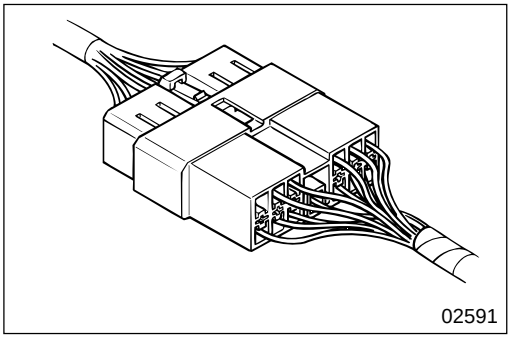


Using male pins

Touch the pins directly using test probes.

CAUTION⚠

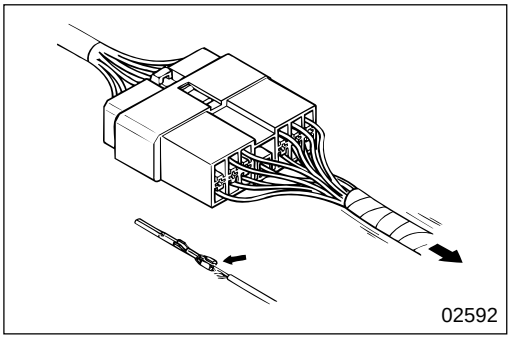
Be sure that you do not short circuit the connector pins when you use the test probe because this could damage the internal circuit of the electronic control unit.



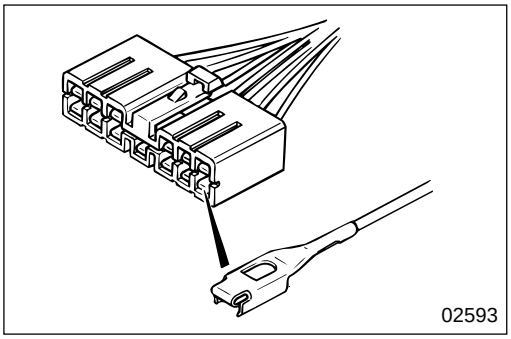
Connector inspection procedures

- **Visual inspection**

  Check for loose connection and poor engagement.

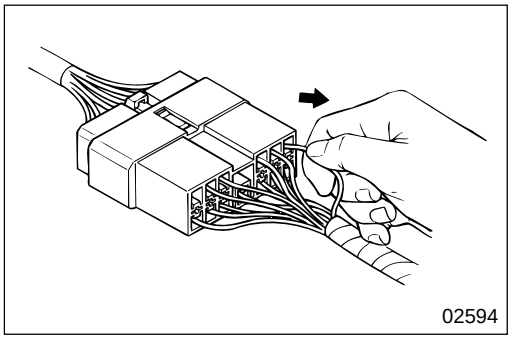


Check if harnesses are broken by pulling gently around the terminals.



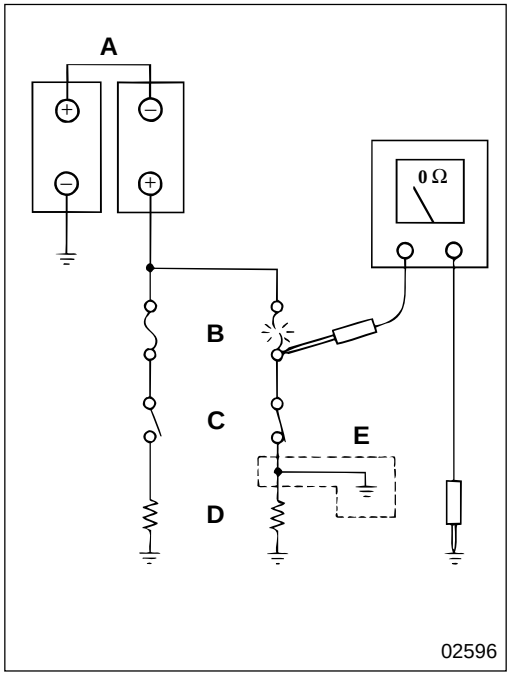
Check for a decrease in contact pressure between the male and female terminals.

Check for poor contact caused by connector pins having fallen out, rusted terminals or foreign particles.



- **Connector pin fall out inspection**

  Damaged connector pin stoppers can cause poor engagement of the terminals (male and female pins) even if the connector body is secured, and might cause some pins to fall out. Check if the pins have fallen out from the connector by pulling each harness gently.



Inspection procedures for blown fuses

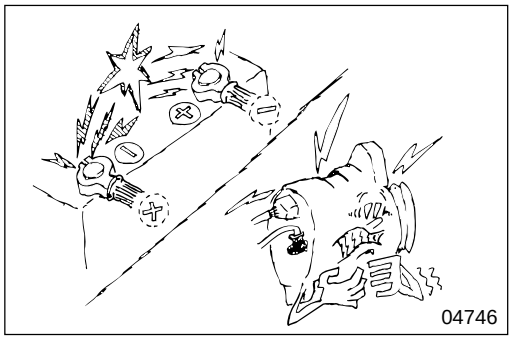
Remove fuse **B** and measure resistance between the loaded side of the fuse and ground.

Turn on all circuit switches (connected to the fuse). If the resistance value reading is approximately 0 Ω, a short has occurred between the switch and the loaded point. A value of other than zero may indicate that the fuse was blown by a temporary short but the short is no longer present.

The major causes of a short circuit are as follows:

- Harness stuck onto the vehicle body.
- Harness sheath damaged by friction or heat.
- Water in connectors or circuits.
- Mistakes (accidental short circuits)

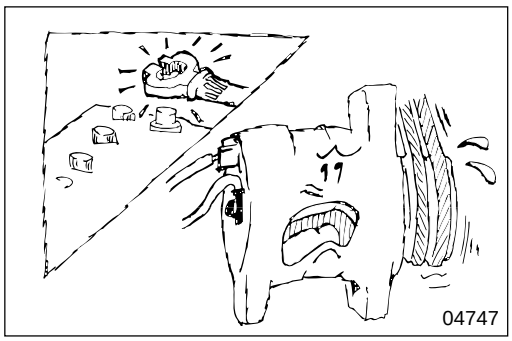
A : Battery
B : Fuse
C : Loaded switch
D : Load
E : Short circuit



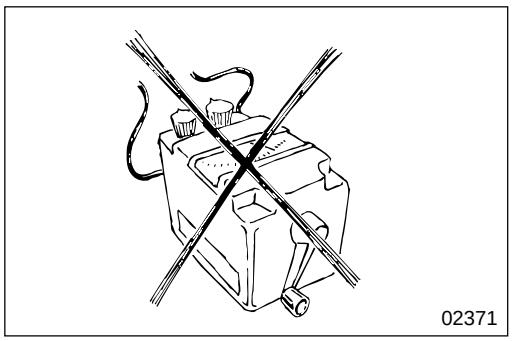
Precautions for handling alternator

When servicing the alternator, pay attention to the following :

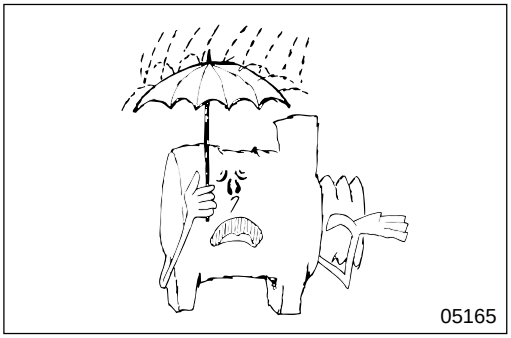
- Do not connect the alternator with battery polarities reversed.
  If the alternator is connected with reversed polarities, a large current flow from the battery to the alternator occurs, and the diode or regulator might be damaged.



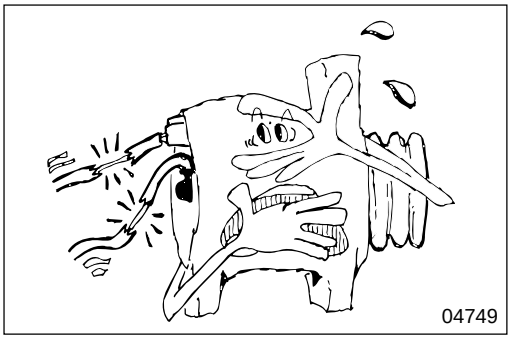
- While the engine is running, do not remove the battery terminals. If the battery terminals are removed at that time, a surge voltage is generated and the diode or regulator might be weakened.



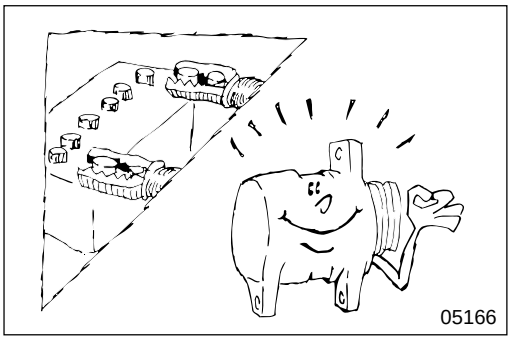
- Do not use a high-voltage tester for inspection.
  If a high-voltage tester is used, the diode or regulator might be destroyed.



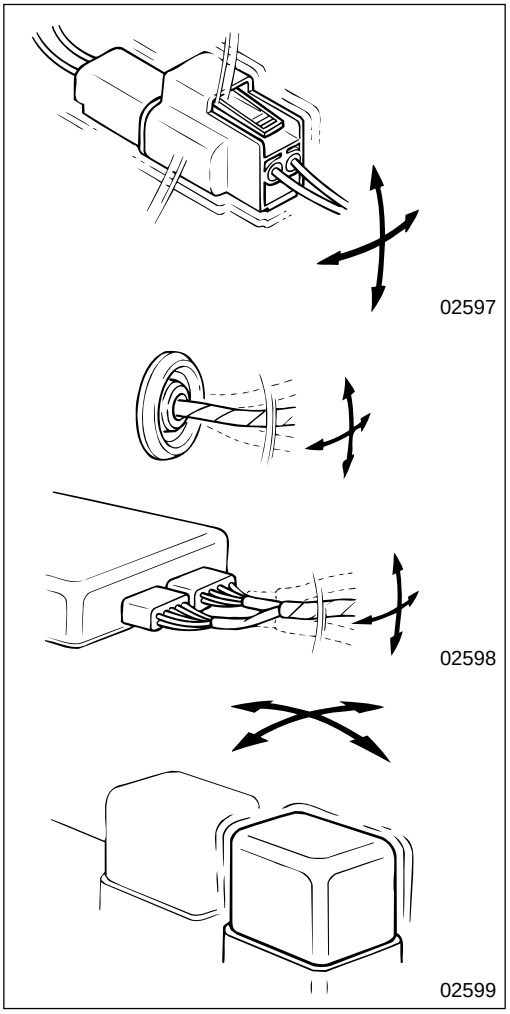
- Do not splash water over the alternator.
  If water is directly splashed over the alternator, individual components will be short-circuited and might be destroyed.



- Do not short-circuit terminal B and terminal L while running the alternator.
  If the terminals are short-circuited while the alternator is running, the diode trio might be destroyed.



- Disconnect the battery terminals before quick-charging the battery. Quick-charging without disconnecting the battery terminals might damage the diode or regulator.



Measures for temporary faults

Temporary faults often occur under certain conditions. So identifying those conditions helps to find possible causes. To find the conditions under which temporary faults occurred, you need to reproduce the faults after interviewing customers in detail about actual driving conditions, weather, frequency of occurence and fault phenomena.
Then determine if the faults were caused by vibration, temperature or other possible elements depending on the actual conditions identified.
If vibration is suspected as a possible cause, inspect individual connectors as follows to check if the fault will occur:

- Shake the connector gently in all four directions of the arrows as illustrated.
- Shake the wiring harness gently in all four directions of the arrows as illustrated.
- Wiggle each sensor or piece of equipment by hand.
- Gently shake the wiring harnesses near movable parts such as suspensions.

The inspection subjects include possible causes related to the diagnosis code outputs and faults, as well as the connectors and other parts in the inspection procedure.

Inspection and maintenance (1)		Time of inspection and maintenance (2)					Working procedures (3)	Remarks (4)
		Pre-operation checks	New vehicle at 4000 km/2500 miles	Inspection interval: Every 10000 km/6000 miles	Every 30000 km/18000 miles *1	Every 60000 km/36000 miles *2		
ENGINE								
1	Air, fuel, oil or coolant leaks from engine			×			Check engine for air, fuel, oil and coolant leaks	Gr 11, 12, 13, 14
2	Ⓔ Ⓝ Engine starting performance, speed, noise and exhaust gas conditions			×			Check for engine starting performance, idling speed, abnormal engine noise, black smoke or other abnormal exhaust gas during idling and acceleration. Check engine speed on tachometer	Gr 11, 13, 15
3	Retightening of inlet and exhaust manifold bolts					×	Retighten, checking of the tightening torque is unnecessary.	Gr 15
4	Ⓔ Val…		×			×	Check valve clearance with fe…	
…	…			Every 20000 km/12000 miles			Replace element	

(1) This column contains the maintenance and inspection items.
(2) The periods between inspection and service are based on the assumption that the vehicle will be driven approximately 60000 kilometers (36000 miles) per year.
Inspections which must be made are indicated by an "×" or by the appropriate period between servicing.
(3) This column provides a simplified explanation of the operational procedures involved for each inspection or maintenance item.
(4) The Gr. No. refers to the "group number" in this vehicle Service Manual. For visual checks and simple inspections, see the sections labelled "Working Procedures".

ENGINE								
1	Air, fuel, oil or coolant leaks from engine			×			Check engine for air, fuel, oil and coolant leaks	Gr 11, 12, 13, 14
2	Ⓔ Ⓝ Engine starting performance, speed, noise and exhaust gas conditions			×			Check for engine starting performance, idling speed, abnormal engine noise, black smoke or other abnormal exhaust gas during idling and acceleration. Check engine speed on tachometer	Gr 11, 13, 15
3	Retightening of inlet and exhaust manifold bolts					×	Retighten. Checking of the tightening torque is unnecessary	Gr 15
4	Ⓔ Valve clearance		×			×	Check valve clearance with feeler gauge	Gr 11
5	Ⓔ Oil filter replacement			Every 20000 km/12000 miles On new vehicle, also replace at the 10000 km/6000 miles			Replace element	P01-7
6	Ⓔ Ⓝ Check injection nozzles			Every 90000 km/54000 miles			Check and clean injection nozzles	Gr 13
7	Ⓔ Ⓝ Fuel injection pressure and spray pattern of injection nozzles			Every 250000 km/150000 miles			Remove injection nozzle and check with nozzle tester	Gr 13
8	Ⓔ Ⓝ Fuel injection timing					×	Turn crankshaft in normal running direction and check injection starting timing of No.1 cylinder	Gr 13
9	Ⓔ Cleaning fuel feed pump gauze filter					×	Remove connector from fuel feed pump inlet and clean filter inside connector with diesel fuel	P01-9
10	Ⓔ Fuel filter replacement				×		Replace element	P01-8
11	Ⓔ Water separator water discharge	×					Loosen water separator drain plug to discharge water	P01-9
12	Ⓔ Draining water and sediment in fuel tank			Every 24 months			Remove fuel tank drain plug and remove water and sediment	Gr 13
13	Retightening the fuel tank bracket bolts			×			Check mounting bolts for looseness and retighten to a torque of 69 to 93 N·m {51 to 69 ft.lbs, 7 to 9.5 kgf·m}	Gr 13
14	Ⓔ Replacing fuel hose in engine compartment			Every 24 months			Replace fuel hose in engine compartment	Gr 13
15	Ⓔ Check fuel line outside the engine compartment			Every 24 months			Check fuel line outside the engine compartment. Replace if necessary	Gr 13
16	Ⓔ Ⓝ V-belt tension and damage	×		×			Press midpoint of V-belt firmly with finger to measure deflection and check for belt damage	P01-11
17	Coolant level and leaks from cooling system	×					Check coolant level and if level is low, check for coolant leaks	Gr 14
18	Coolant replacement			Every 24 months			Replace with new coolant	Gr 14
19	Radiator cap condition			×			Check radiator cap for sealing and mounting condition	Gr 14
20	Ⓔ Cooling system hose clamp position and clamping condition			×			Check clamp position and clamping condition of cooling system hose	Gr 14
21	Ⓔ Turbocharger rotor play			Every 250000 km/150000 miles			Check rotor for excessive end play by using a dial indicator	Gr 15
22	Ⓔ Ⓝ Cleaning of air cleaner element	×		×			Check air cleaner dust indicator. If red signal appears, clean the element	P01-13
23	Ⓔ Ⓝ Air cleaner element replacement			Every 50000 km/30000 miles			Replace element	P01-13
24	Ⓔ Ⓝ Damage of air intake system, looseness of clamp and loss of parts			×			Check air intake system for damage and inspect all parts for installation	Gr 15
25	Ⓔ Ⓝ Exhaust system			×			Check the exhaust system for damage, corrosion and loose connection causing leakage	Gr 15
26	Starter function					×	Operate starter switch and check the switch for proper function	Gr 54
27	Alternator function					×	Check for function with a circuit tester	Gr 54

POWER TRAIN								
28	Air or oil leaks from power train			×			Check power train for air and oil leaks	
29	Clutch pedal play			×			Press clutch pedal lightly and check that its play is adequate	🕮 P01-14
30	Clutch function			×			(1) Press the clutch pedal to check for unusual noise or stiffness. Also check if gear engages quietly (2) Check the clutch does not slip and engages smoothly	🗀 Gr 21
31	Manual transmission gearshift control looseness				×		In NEUTRAL position, check gearshift lever for looseness. With gearshift lever in each gear position, check all gears engage smoothly without excessive looseness. Also check that control cable in not damaged	🗀 Gr 22A, B
	Automatic transmission range selector linkage and throttle (modulator) linkage condition				×		Shifting to each position must be correct and secure	🗀 Gr 23A, B
32	Propeller shaft couplings and bearings looseness		×	×			(1) Check flange yoke bolts and center bearing bolts for looseness (2) Turn propeller shaft manually to check for loose spline coupling (3) Check for looseness between spider and needle roller bearing On new vehicle inspection at 4000 km/2500 miles, check only the looseness of bolts	🗀 Gr 25
FRONT AND REAR AXLES								
33	Axle shaft torsion and cracks					×	Remove axle shaft and check for torsion, bend, and cracks	🗀 Gr 27
34	Front wheel hub bearing looseness				×		With front axle jacked up, move wheel up and down by holding tire's top and bottom to check for bearing looseness	🗀 Gr 26
35	Rear wheel hub bearing damage					×	Disassemble rear wheel and check for hub bearing wear and damage	🗀 Gr 27
36	Retightening wheel nuts		×	×			Check wheel nuts for looseness	🕮 P01-15
37	Disc wheel damage			×			Check disc wheel for corrosion, deformation and cracks	🗀 Gr 31
38	Tire inflation pressure, cracking, tread groove depth, abnormal wear, etc.	×		×			(1) Measure inflation pressure with tire pressure gauge, und check that tire tread groove is deep enough (2) Check tire tread and side walls for cracks, damage, uneven ridgy and other abnormal wear	🕮 P01-15
39	Tire rotation			×			Rotate all tires	🕮 P01-15
SUSPENSION SYSTEM								
40	Looseness, play and damage of suspension system				×		Check suspension system for looseness, play and damage	🗀 Gr 33, 34
41	Damage and looseness of leaf springs	×			×		Check leaf springs for damage and looseness	🗀 Gr 33, 34
42	Retightening U-bolts		×		×		Check U-bolts for looseness	🗀 Gr 33, 34
43	Oil leaks and damage of shock absorbers				×		Check for oil leaks from and damage of cylinders and other parts	🗀 Gr 33, 34
BRAKING SYSTEM								
44	Air pressure and its charging speed	×					After discharging air from air tank, start and run the engine at idle and measure time taken to charge air to specified pressure in air tank	🗀 Gr 35A, B
45	Air and fluid leaks from braking system			×			Check braking system for air and fluid leaks	🗀 Gr 35A, B
46	Looseness, play and damage of braking system parts			×			Check braking system parts for looseness, play and damage	🗀 Gr 35A, B
47	Condensation in air tank	×					Open drain cock and check for presence of condensation in air tank	🗀 Gr 35A, B

48	Operation of brake pedal			×			Depress the brake pedal and release it, checking for the sound of air being released from the brake valve and to ensure that the pedal returns normally without cathing Press the brake pedal with a finger to the point where resistance is felt and meassure the distance (play) over which the pedal has moved	Gr 35A, B
49	Foot brake effectiveness	×		×			While driving the vehicle at low speed, check braking effect and check for uneven braking	Gr 35A, B
50	Operation of exhaust brake	×		×			Check exhaust brake operation	Gr 35A, B
51	Exhaust brake control cylinder packing replacement			Every 12 months			Check exhaust brake control cylinder packing; replace if necessary	Gr 35A, B
52	Operation of air dryer			×			Open drain cock of air tank and make sure there is no drainage.If there is a small amount of drainage from the FK series, remove the plug from the air dryer and check the color of the indicator. If it is pink, drying agent	Gr 35A, B
53	Check drain from air dryer exhaust port			×			Check to see that oil is not discharged abnormally from exhaust port of air dryer	Gr 35A, B
54	Air dryer disassembly and check					×	FK series : Remove plug from the air dryer and check color of indicator. If indicator is pink, disassemble and replace drying agent FM series : Disassemble air dryer and check every part of it. If more than 1/5 of the drying agent is discolored, replace drying agent	Gr 35A, B
55	Replacement of drying agent in air dryer			Every 24 months			Disassemble air dryer and replace drying agent and rubber parts	Gr 35A, B
56	Brake shoe clearance				×		Measure clearance with feeler gauge *3 *5	Gr 35A, B
							Measure brake chamber push rod stroke *4	
57	Brake lining wear				×		Check for lining wear	Gr 35A, B
58	Brake drum wear					×	Disassemble and check drum for wear, cracks and damage	Gr 35A, B
59	Slack adjuster cracking *4					×	Check slack adjuster for cracking and other damages	Gr 35B
60	Parking brake effectness			×			On a slope, check that vehicle can be held stationary	Gr 36A, B
61	Parking brake operation *4 *5	×		×			(1) Check for operation of parking brake control valve (2) Check operation when brake line air pressure is reduced	Gr 36B
62	Parking brake lever stroke *3	×		×			With lever full pulled, check that lever is locked completely and that there is allowance in pulling stroke	Gr 36A
63	Parking brake drum and lining wear *3					×	Disassemble and check drum for wear, cracks and damage and lining for wear	Gr 36A
64	Brake chamber expander boot inspection*5					×	Check expander boot for damage	Gr 35B
65	Wheel cylinder piston cup and dust seal replacement *3			Every 12 months			Check wheel cylinder piston cup and dust seal; replace if necessary	Gr 35A
66	Brake booster packing, cup and rubber parts replacement *3			Every 12 months			Check brake booster packing, cup and rubber parts; replace if necessary	Gr 35A
67	Brake hose replacement			Every 12 months			Check brake hose; replace if necessary	Gr 35A, B
68	Check valve packing and rubber parts replacement			Every 12 months			Check check valve packing and rubber parts; replace if necessary	Gr 35A, B
69	Brake valve packing and rubber parts replacement			Every 12 months			Check brake valve packing and rubber parts; replace if necessary	Gr 35A, B
70	Air compressor and pressure gauge hoses replacement			Every 24 months			Replace air compressor and pressure gauge hose	Gr 35A, B
71	Brake booster power cylinder packing replacement *3			Every 24 months			Replace brake booster power cylinder packing	Gr 35A
72	Brake fluid reservoir tank tube replacement *3			Every 24 months			Check and replace brake fluid reservoir tank tube	Gr 35A

STEERING SYSTEM								
75	Fluid leaks from steering system			×			Check steering system for fluid leaks	Gr 37
76	Steering wheel play	×		×			Turn steering wheel right and left to measure play at steering wheel rim. Measure while engine is running	Gr 37
77	Steering operating condition	×		×			Check steering wheel to see if it vibrates, pulls to one side or requires unusual steering effort	Gr 37
78	Looseness and play of steering system (including hoses and pipes)			×			(1) Check steering system for looseness and play (2) Check power steering hoses and pipes for looseness	Gr 37
79	Wheel alignment					×	Measure toe-in, camber, caster and kingpin inclination angles	Gr 26
80	Right and left turning angles and power steering function					×	(1) Check that the stopper bolt is sufficiently tight, without damage, and that steering linkage operates smoothly until blocked by stopper bolt (2) Check that steering wheel does not contact other parts	Gr 26
81	Power steering booster and oil pump internal rubber parts replacement			Every 48 months			Replace internal rubber parts	Gr 37
82	Power steering hose replacement			Every 48 months			Replace power steering hose	Gr 37
CAB AND FRAME								
83	Looseness and damage of chassis and body			×			(1) Check the frame, cross members and other parts for cracks and damage, also check for loose rivets (2) Also check for body damage and loose mounting bolts	Gr 41, 42
84	Heater and defroster operation			×			Check operation and installation of defroster	Gr 55B
85	Reflection of rearview mirrors and reflectors	×					Check for reflecting condition, stains and damage	Gr 42

ELECTRICAL SYSTEM								
88	Looseness and damage of electrical wiring and connections			×			Check wiring, connectors and battery terminals for looseness and corrosion	Gr 54
89	Battery electrolyte level and specific gravity			Every 20000 km/ 12000 miles			(1) Check electrolyte level (2) Measure electrolyte specific gravity with hydrometer	Gr 54
90	Operation and damage of the lighting system and turn signal lamps	×		×			(1) Check operation, damage and installation of each lighting unit (2) Check that turn signal lamps are operated by the turn signal switch	Gr 54
91	Operation of horn	×		×			Check operation, damage and mounting condition	Gr 54
92	Operation and fluid level of windshield wiper and washer	×		×			Check operation, damage and mounting condition Check if fluid level in washer tank is okay	Gr 42
93	Gauges and pilot lamps function	×		×			Check function of gauges and pilot lamps	Gr 54
94	Switch function					×	Check operation, damage and installation of each switch	Gr 54
OTHER								
95	Road test of vehicle			×			Drive the vehicle to check for overall vehicle operating condition	

This section explains simple maintenance procedures. See the relevant Group in this manual for further details.

Replacement of Oil Filter

Lubricant

Location	Points of application	Kinds	Quantity
2	Inside oil filter	Engine oil	Approximately 2.3 L {2.4 qts}
	Gasket area of oil filter with thin application	Engine oil	As required

Special tools

Unit : mm {in.}

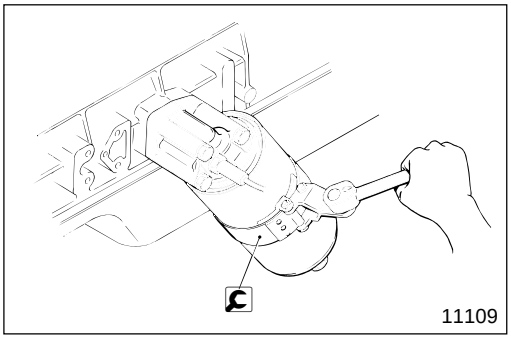
Location	Tool name and shape	Part No.	Application
2	Oil filter wrench  01503	MH061537 (Obtain Locally)	Removal of oil filter

WARNING

- **Wipe up any engine oil that has been spilled because it can cause a fire.**
- **Do not touch the engine while it is hot because it will burn you.**

CAUTION

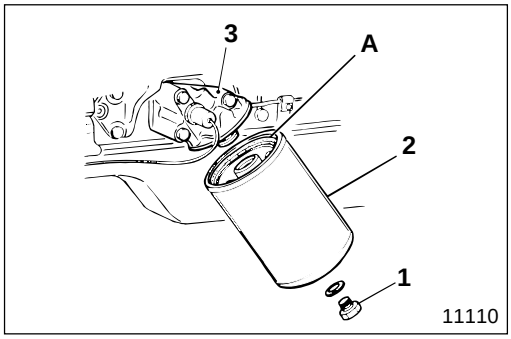
Take care not to spill engine oil on the V-belts, because this would cause them to slip, reducing service life.



11109

[Removal]

: Oil filter wrench



11110

[Installation]

- Clean the surface of oil filter head **3** that makes contact with oil filter **2**.
- Apply engine oil thinly and evenly to gasket area **A** of oil filter **2**.
- Screw in oil filter **2** to oil filter head **3** until gasket area **A** sits on the filter head. From this position, tighten further by rotating by one and one eighth to one and three eighths of a turn.
- After installation, run the engine and check that there is no oil leakage from gasket area **A**.
- Check the oil level and if it is low, top it up.

Replacement of Fuel Filter

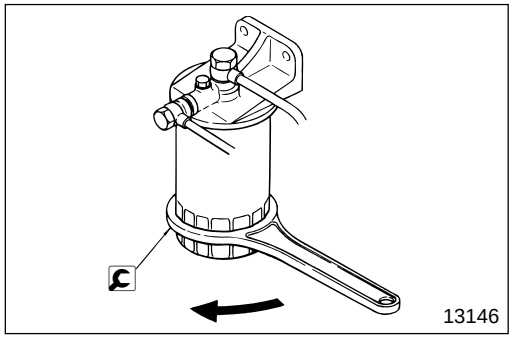
Lubricant

Location	Points of application	Kinds	Quantity
2	Gasket contact surfaces of fuel filter and fuel filter head	Engine oil	As required

Special tools

Unit : mm {in.}

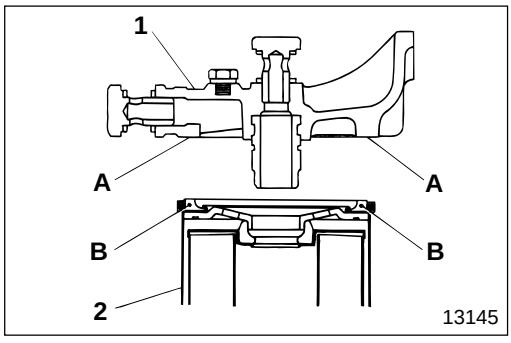
Location	Tool name and shape	Part No.	Application
2	Filter wrench  01882	MH061572 (Obtain Locally)	Removal of fuel filter



13146

WARNING
- **Fuel ignites easily. Do not get it near flame or heat.**
- **Wipe up any gas oil that has been spilled because it can cause a fire.**
- **Do not use an unsuitable filter because it can cause a fire.**

[Removal]
: Filter wrench



13145

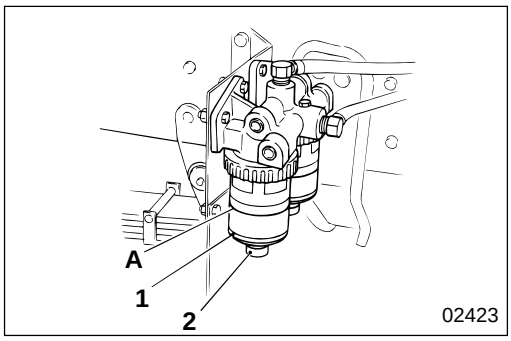
[Installation]
- Install by tightening by three quarters to one full turn after contact surface **A** of fuel filter head **1** contacts gasket **B** of fuel filter **2**. Be sure to tighten by hand.
- After installation, run the engine and check for fuel leakage.

Draining of Water Separator Condensation

Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
2	Drain plug	2.9 to 3.9 {2.2 to 2.9, 0.3 to 0.4}	—



Visually inspect the water separator before driving.
When float **1** reaches red line **A**, drain the condensation as follows:

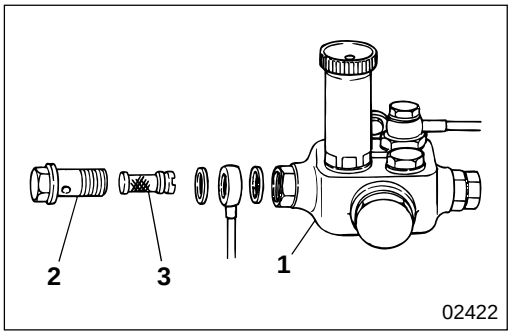
- Loosen drain plug **2** and drain out the condensation.
- When float **1** has dropped to the bottom, tighten drain plug **2**.
- Carefully wipe the water separator and the surrounding area.
- Check for fuel leakage.

Cleaning of Fuel Feed Pump Mesh Filter

Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
2	Eye bolt	25 to 29 {18 to 22, 2.5 to 3}	—



WARNING

- **Fuel ignites easily. Do not get it near flame or heat.**
- **Wipe up any gas oil that has been spilled because it can cause a fire.**
- **Do not use an unsuitable filter because it can cause a fire.**

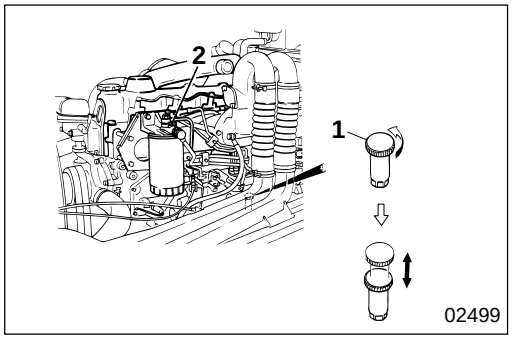
- Remove eye bolt **2** on the inlet side of fuel feed pump **1**.
- Remove mesh filter **3** from eye bolt **2**.
- Clean gauze filter **3** with gas oil.
- Follow the removal sequence in reverse and reinstall gauze filter **3**. Install eye bolt **2** in the fuel feed pump.
- Bleed the air from the fuel line.
- Start the engine and check for fuel leakage.

Bleeding of Air from Fuel Line

Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
2	Air vent plug	7.8 to 12 {5.8 to 8.7, 0.8 to 1.2}	—



WARNING

- **Fuel ignites easily. Do not get it near flame or heat.**
- **Wipe up any gas oil that has been spilled because it can cause a fire.**

- Turn the top of priming pump **1** of the injection pump counterclockwise and pull it up so the top protrudes.
- Loosen air vent plug **2** of the fuel filter and move the top part of priming pump **1** up and down.
- Move priming pump **1** up and down repeatedly until air bubbles are no longer present in the fuel drained from air vent plug **2**.
- When the fuel being drained is free of air bubbles, tighten air vent plug **2**.
- After moving priming pump **1** up and down another five or six times, push the top down and turn clockwise to drive it in fully.
- After bleeding the air, carefully wipe up spilled fuel and start the engine.
- Check for fuel leakage.

Adjustment of V-Belt Tension

Newly installed V-belts can stretch during their initial running-in period. To prevent this from becoming a problem, run the engine for several minutes after installing the V-belt, then readjust. Perform this cycle several times.

WARNING⚠

You must take special precautions to prevent the engine from rotating while a V-belt is being inspected or adjusted.

CAUTION⚠

- **Make sure that you turn off the engine before attempting to inspect or adjust the V-belts.**
- **Make sure that you fasten all bolts and nuts securely after adjusting the V-belts. Remember that too much tension can damage the V-belts and bearings.**
- **Do not grease V-belts. This causes them to slip, which reduce service life.**

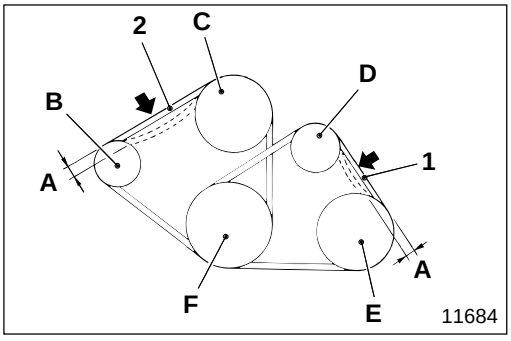
Service standards

Unit : mm {in.}

Location	Maintenance item		Standard value	Limit	Remedy
1, 2	V-belt Flex (Each)	Fan	10 to 15 {0.39 to 0.59}	—	Adjust
		Air-conditioner	7 to 10 {0.28 to 0.39}		

Special tools

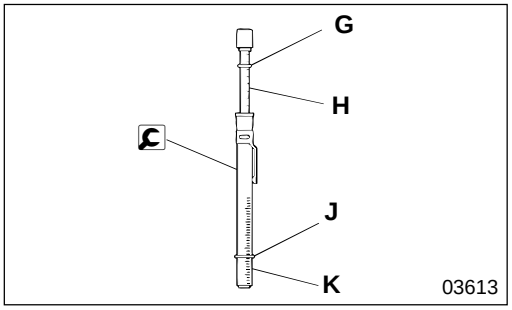
Location	Tool name and shape	Part No.	Application
1, 2	Belt tension gauge 03612	MH062345	Measurement of tension of V-belt



[Inspection]

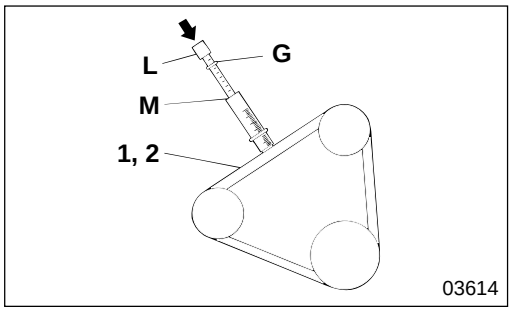
Measure the extent of flex **A** when the center of V-belts **1**, **2** as illustrated is depressed with a force of 98 N·m {72 ft.lbs, 10 kgf·m}.

B : Alternator pulley
C : Water pump pulley
D : Tension pulley
E : Cooler compressor pulley (Air-conditioner)
F : Crankshaft pulley

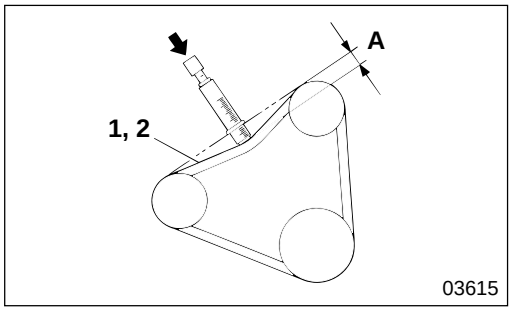


Use of special tool belt tension gauge

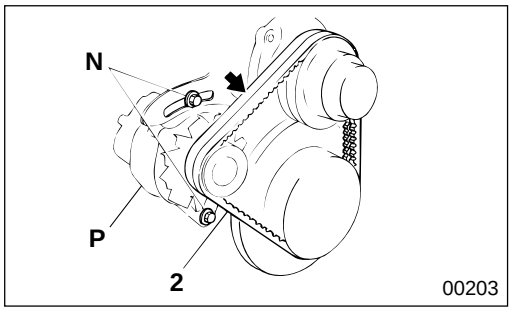
- Set upper O-ring **G** of 🔧 belt tension gauge to 98 N·m {72 ft.lbs, 10 kgf·m} (push load) on graduation **H**.
- Set lower O-ring **J** of 🔧 belt tension gauge to graduation **K** (maximum flex of belt).



- Place 🔧 belt tension gauge at the center of V-belts **1**, **2** perpendicularly as illustrated and push top **L** all the way down until upper O-ring **G** hits upper edge **M**.



- Measure the extent of flex **A** of V-belts **1**, **2** at this point, and if the measured value deviates from the standard value, adjust as follows:



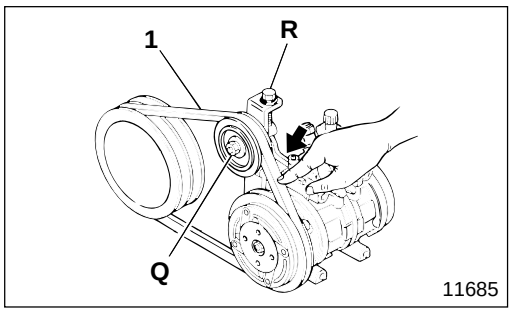
[Adjustment]

(1) Adjustment of tension of V-belts for fan

- Loosen alternator mounting bolts **N** (two points).
- Adjust the tension of V-belt **2** by rocking alternator **P** left and right.
- After adjustment, tighten mounting bolts **N** securely.

CAUTION⚠

- **Bear in mind that excessive tension of V-belts 2 might damage the belts and bearings that engage with the V-belts.**
- **Be sure to replace V-belts 2 as a set to maintain even tension between them.**
- **Be careful not to let oil stick to V-belts 2. If oil gets onto the belts, it causes slipping, resulting in overheating and insufficient battery charging.**



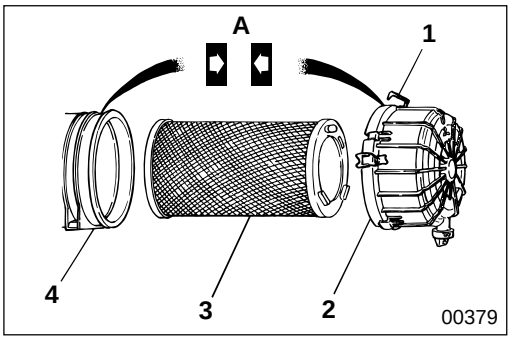
(2) Adjustment of tension of V-belt for air-conditioner

- Loosen tension pulley mounting nut **Q**, and adjust the tension of V-belt **1** moving adjusting bolt **R**.
- After adjustment, tighten mounting nut **Q** securely.

CAUTION⚠

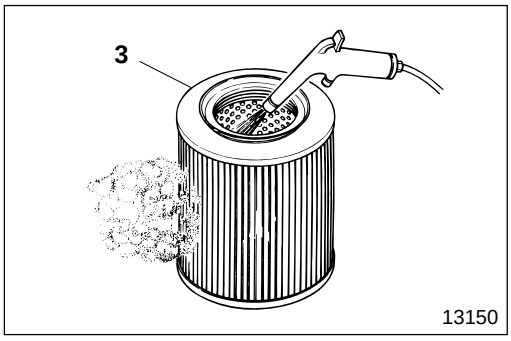
- **Bear in mind that excessive tension of V-belt 1 might damage the belt and bearings that engage with the V-belt.**
- **Be careful not to let oil stick to V-belt 1. If oil gets onto the belt, it causes slipping, resulting in poor performance of the air-conditioner.**

Cleaning and Replacement of Air Cleaner Element



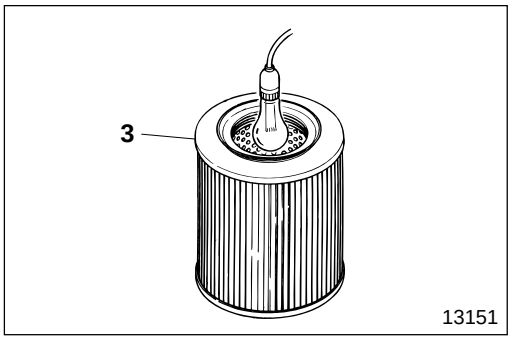
[Removal]
- Remove clamp **1** to remove cover **2**.
- Remove air cleaner element **3**.

[Installation]
Install case **4** and cover **2** by aligning arrows **A**.



[Cleaning]
- Blow compressed air of 685 kPa {100 psi, 7 kgf/cm^2} or less through air cleaner element **3** from the inside.
- When using compressed air, move the blower's nozzle up and down along the pleats of air cleaner element **3** evenly.

CAUTION⚠
- **Do not tap or hit air cleaner element 3 to remove dust.**
- **Do not blow compressed air through air cleaner element 3 from the outside.**



[Inspection]
- Illuminate the inside of air cleaner element **3**.
- If parts of the filter paper are torn or thin, or if the packing of the upper surface of air cleaner element **3** is damaged, replace the air cleaner element.

NOTE

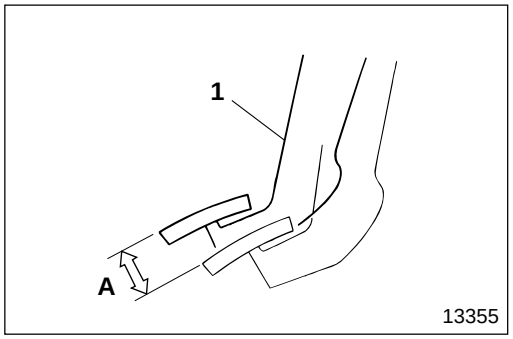
If the dust on air cleaner element 3 is wet due to oil smoke or soot, replace the air cleaner regardless of the scheduled replacement interval.

Inspection of Clutch Pedal Free Play

Service standards

Unit : mm {in.}

Location	Maintenance item		Standard value	Limit	Remedy
1	Clutch pedal free play	Except for FM657 (M8S2×5)	32 to 44 {1.26 to 1.73}	—	Adjust or replace
		FM657 (M8S2×5)	25 to 37 {0.98 to 1.46}	—	



[Confirmation]
Push clutch pedal **1** with your hand and measure the amount of movement **A** (free play) until you meet resistance. If the measured value does not conform to the standard value, adjust the stroke of the clutch power cylinder or the clutch booster push rod, or replace the clutch disc.

[Clutch operation]
- Check for unusual noises when clutch pedal **1** is pressed while the engine is idling, and also for abnormally heavy clutch operation. Also check to be certain that it is not difficult to shift the vehicle into first and reverse gears.
- Gradually release clutch pedal **1** to set the vehicle in motion.
  Check to be sure there is no slippage, and that the clutch engages smoothly.

Tire

Service standards

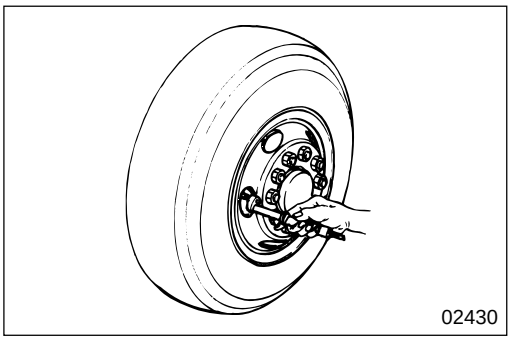
2	Wheel nut spherical area	Chassis grease [NLGI No.1 (Ca soap)] or Wheel bearing grease [NLGI No.1 (Li soap)]	As required
4	Wheel nut (inner) at thread area and spherical area		
6	Thread area of hub bolt		



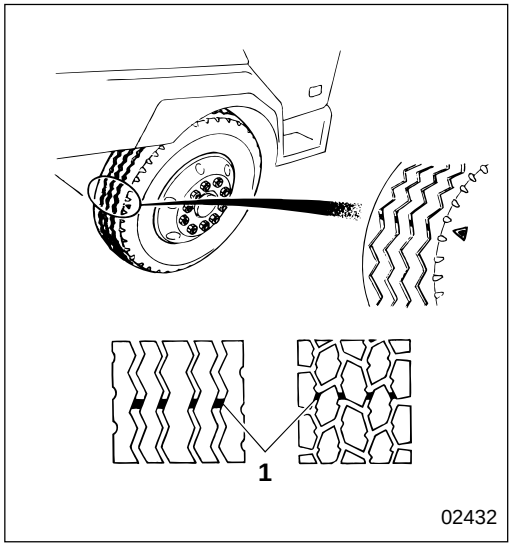
Air pressure

Tire air pressure should be checked before the vehicle is driven, while the tires are still cool.

Model	Tire size	Air Pressure kPa {psi, kgf/cm^2}
FK	9R 22.5-12PR	Front : 750 {105, 7.50} Rear : 675 {95, 6.75}
FM	11R 22.5-14PR	

CAUTION

- **Make certain that there is no difference in the air pressure between the inner and outer rear tires.**
- **Make certain you use valve caps on the air valves.**
- **It is not necessary to increase the air pressure for high-speed driving.**

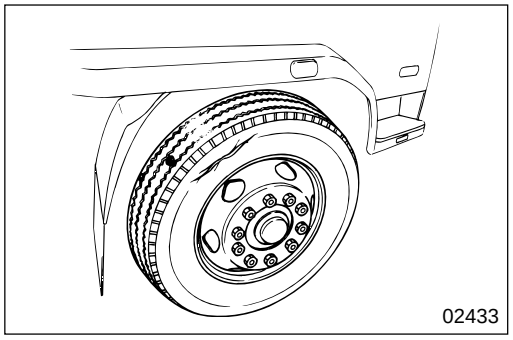


Checking tread depth

- Check the circumference of the tire to make sure that the depth of the tread grooves is above the wear limit.
- If the tread grooves are not deep enough, wear indicator **A** appears at the position of the ⚠ mark, where the tread groove has worn away.

WARNING⚠

If the depth of the tread grooves is not adequate, the tires will slip on wet roads and present a hazard. Such tires are also extremely dangerous because they are more susceptible to hydroplaning when the vehicle is running at high speeds in the rain. Such tires must be replaced with new ones as soon as possible.



Checking for cracks, damage, and objects embedded in the treads

- Check the tire treads and walls for cracks and damage.
- Check tire treads for uneven wear or other abnormal wear.
- Check if metal objects or nails have penetrated the tires.
- Check for stones embedded between double tires.

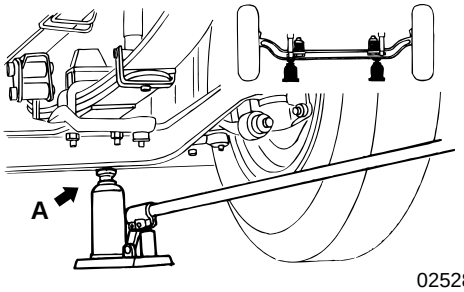
WARNING⚠

Badly damaged or worn tires are extremely dangerous, because they can be punctured more easily when the vehicle is running, they must be replaced with new ones as soon as possible.

Removing tires

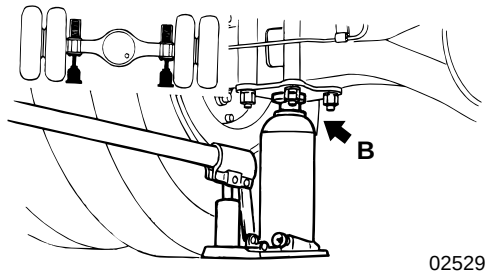
- Jacking up point
  - For front wheels : Front axle bottom A
  - For rear wheels : Rear axle tube bottom B

< Front wheel >



02528

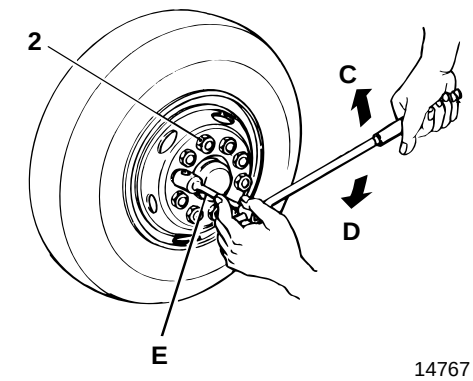
< Rear wheel >



02529

WARNING

- **The jack should be placed on flat, solid ground, and should not be used to raise the vehicle higher than necessary.**
- **Do not use the jack at vehicle locations other than those illustrated.**
- **Keep in mind the danger of a slipping jack. Never crawl under the vehicle while the jack is in use or rock the vehicle. Also, do not start the engine while the vehicle is jacked up.**
- **To increase safety, use supports for the vehicle when it is necessary to leave it jacked up for long periods.**
- **Chock both the tire to be removed and the tire diagonally opposite to it so that they will not rotate when you are removing the tire.**



14767

- Loosen wheel nuts **2** slightly. The wheel nuts for right tires **C** have right-hand threads "**R**", and the wheel nuts for left tires **D** have left-hand threads "**L**".

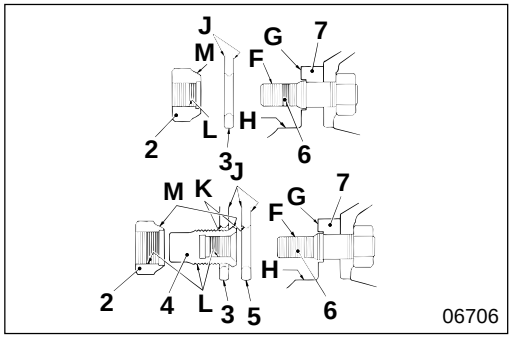
WARNING

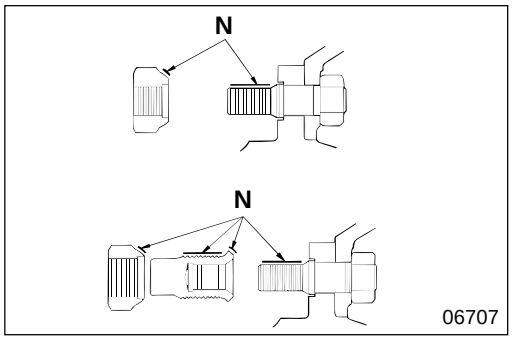
Make certain that wheel nut wrench E is fully engaged, all the way to the back of nuts 2. If it is not, it could slip.

CAUTION

Only loosen wheel nuts 2 slightly. Do not remove them.

- Jack up the vehicle carefully, until the tire is slightly off the ground. Remove wheel nuts **2**, then remove the tire.
- When working on the double tires at the rear of the vehicle, first remove the outside tire, then lower the vehicle and loosen the nuts on the inside tire. After doing this, jack the vehicle back up and remove the tire.



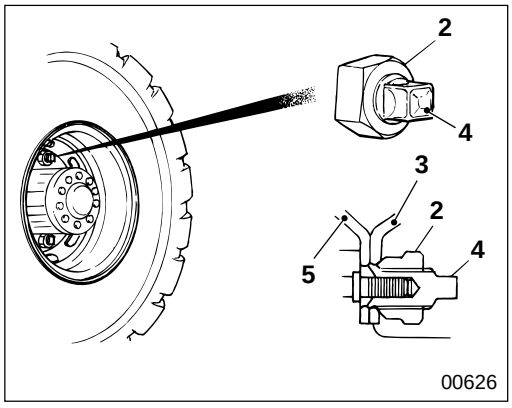


Mounting tires

- To prevent wheel nuts **2**, **4** and hub bolt **6** from becoming loose and to prevent mounting parts (tire assemblies **3**, **5** and hub **7**) from being damaged, remove rust, dust, additional coatings of paint, and foreign particles from the following areas:
  F : Hub bolt thread area
  G : Wheel mounting surface of hub
  H : Wheel alignment area of hub
  J : Disc wheel mating surface
  K : Disc wheel nut mounting surface
  L : Wheel nut thread area
  M : Wheel nut spherical area
  N : Grease application area

WARNING⚠

Never use grease containing molybdenum disulfide, because it would cause loosening of fitted screws.



- Put on the dual rear tires as follows:
  - After mounting inner tire **5** and fully tightening inner wheel nuts **4**, jack the vehicle up and mount on outer tire **3**, then tighten outer wheel nuts **2**.
  - Even if only outside tire **3** is to be changed, do not mount it until inner wheel nuts **4** have been fastened at the specified torque.
  - Slide the air valves on the inside and outside tires down when mounting the tires.

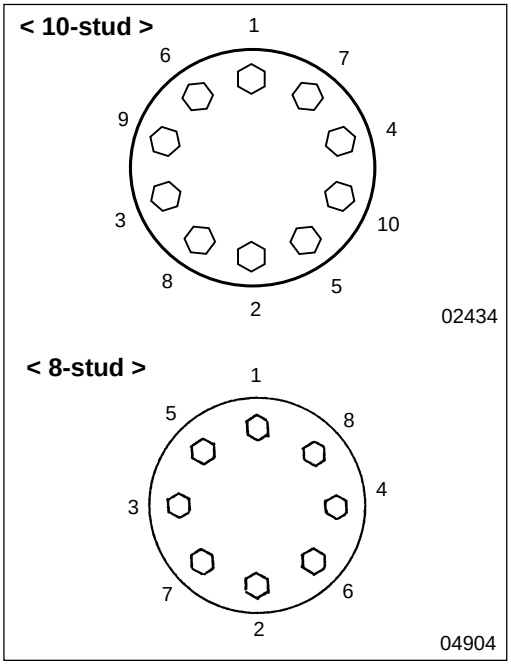
WARNING⚠

If the threads are scored, or the disc wheel is deformed or cracked, change bolts 6, nuts 2, 4 and disc. Driving the truck before correcting such problems can cause the tire in question to come loose, which could be the source of major accidents.

CAUTION⚠

Check hub bolt 6 threads carefully for scratches before putting the tire on.

- Place the tapered end of wheel nuts **2**, **4** towards the disc wheel and fasten temporarily. Center so that there is no eccentricity between bolts **6** and the disc wheel bolt holes.
- Lower the vehicle.



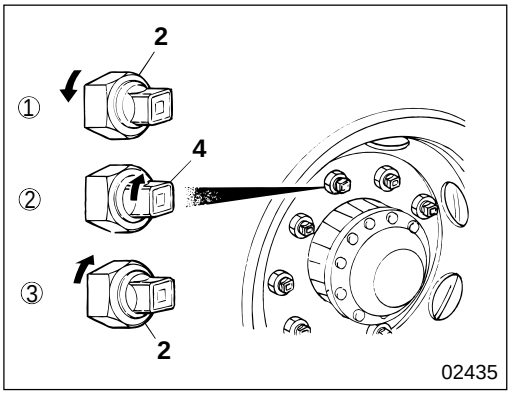
- Tighten the nuts in the order as illustrated, tightening each nut two or three times. To finish, tighten each nut at the specified torque.

WARNING⚠

Always use the specified torque when tightening the wheel nuts. If the wheel nuts are not tightened properly, the wheels could come loose while the vehicle is being driven, which could result in life threatening accidents or the truck being disabled.

CAUTION⚠

Over-tightening the wheel nuts can damage them.



Checking the wheel nuts for looseness

The wheel nuts should be checked for looseness every 10000 km (6000 miles). All the nuts should be tightened at specified torque.

- Check the double rear tires for looseness as follows:

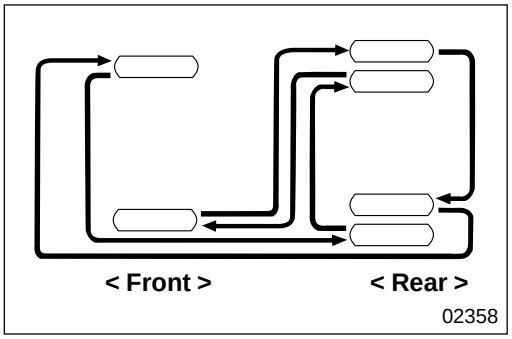
① Loosen outer wheel nuts **2**.
② Tighten inner wheel nuts **4** at specified torque.
③ Tighten outer wheel nuts **2** at specified torque.

CAUTION⚠

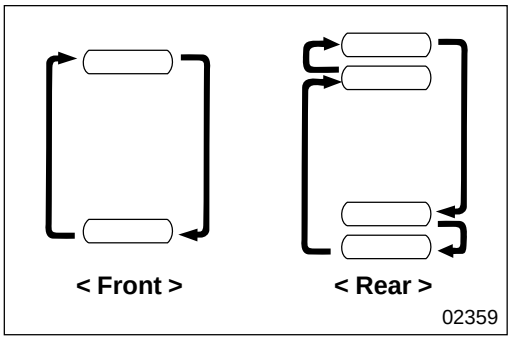
If outer wheel nuts 2 are tightened without first being loosened, it might not be possible to tighten them at the specified torque.

Tire rotation

Tires wear differently, according to the location where they are mounted. To make this wear uniform and prolong the life of your tires, they should be rotated every 10000 km (6000 miles) in the rotation order shown below:



- When the tread patterns for all tires are identical:



- When the tread patterns are different for the front and rear tires:

CAUTION ⚠

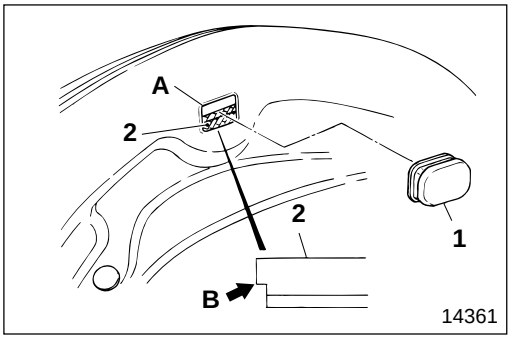
- **Always adjust air pressure after running-in new tires.**
- **When using tires of different tread patterns, use rib-type patterns for the front tires and traction type patterns for the rear tires.**
- **Avoid using both radial and biased tires on the same vehicle.**

Inspection of Brake Lining Thickness

Service standards

Unit : mm {in.}

Location	Maintenance item		Standard value	Limit	Remedy
2	Thickness of brake lining	FK617, FM617	—	5.5 {0.22} (Side shoulder means wear limit)	Replace
		FM657	—	6 {0.24} (Side shoulder means wear limit)	Replace



NOTE

Be sure to inspect at two points for each wheel per side.

- Remove check hole plug **1** from the backing plate.
- Inspect through check hole **A** whether brake lining **2** is worn to the point of side shoulder (wear indicator) **B** of the brake lining (the limit).
- If the measured value is lower than the limit, replace brake lining **2** on both sides of the axle.
- After inspection, be sure to reinstall check hole plug **1**.

Battery

DANGER ⚠

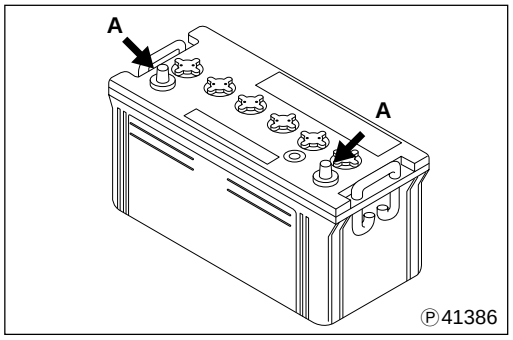
- **Since flammable hydrogen gas is generated by the battery, be sure to obey the following warnings:**
  - **Do not short-circuit the ⊕ and ⊖ terminals on the battery.**
  - **Keep sparks and lit cigarettes away from the battery.**
  - **Do not wear metal objects on your arms and lean over the bat tery.**
- **Because the battery electrolyte is diluted sulfuric acid and is corrosive when handling the battery wear safety glasses and rubber gloves to protect the eyes and hands.**
- **Battery posts, terminals and related accessories contain lead and lead compounds. Wash hands after handling.**

WARNING ⚠

To prevent a short-circuit be sure that disconnected the battery cables do not accidentally touch the battery terminals.

CAUTION ⚠

- **Make sure that you disconnect the battery cable ⊖ first when you disconnect the battery cables.**
- **Make sure that all electrical switches of the vehicle are OFF before connecting the battery cables.**
- **Make sure that you connect the battery cables ⊕ before you connect the battery cable ⊖.**

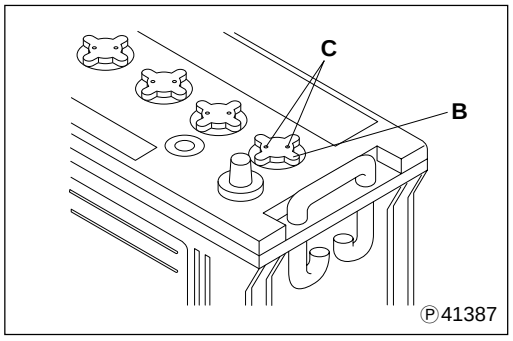


Visual inspection

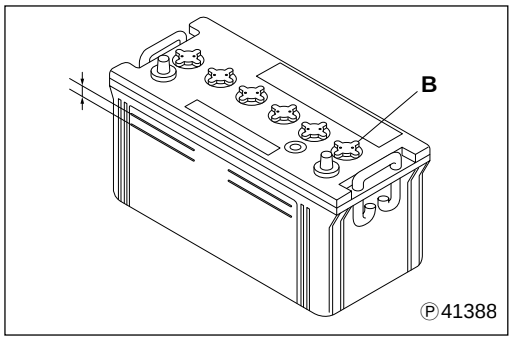
- If terminal **A** is corroded, scrub off the corrosion using a wire brush.
- If cracks or defects are found on the battery, replace it since the cracks or defects can cause liquid spills.

CAUTION⚠

Make sure you grease the ⊕ side of terminal A because it is easily corroded.

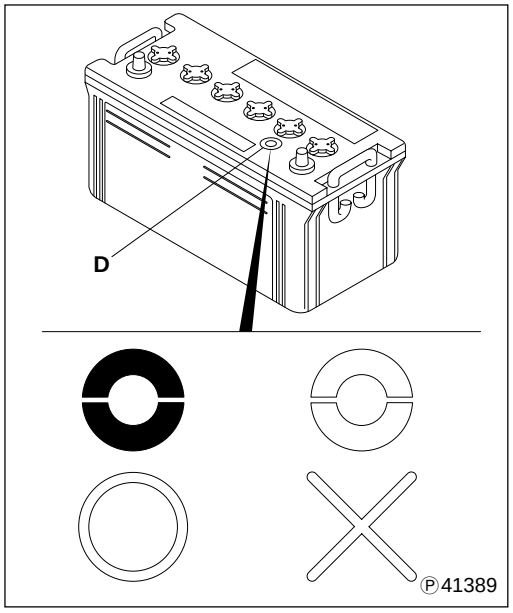


- If bleed hole **C** of vent plug **B** is clogged, clean the hole.



Inspection of fluid level

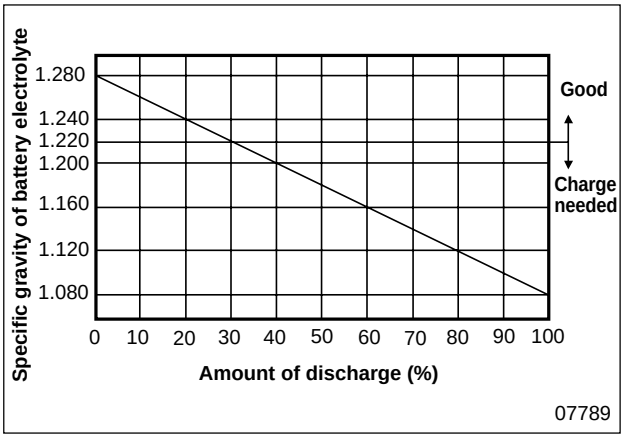
- Make sure that the battery electrolyte level is between the UPPER and LOWER level lines.
- If the level is below the LOWER level line, remove vent plug **B** and fill the battery with distilled water or battery replenisher to the UPPER level line.



Measurement of specific gravity

You can tell the specific gravity of the battery electrolyte by the color shown in indicator **D**.

Blue : Good
White : Charge or replace



Charging

- Although, as a rule, charging of the battery should be done with the battery removed from the vehicle, if you have to charge the battery while it is on the vehicle, make sure that you stop the engine and disconnect the battery cable ⊖.
- Remove vent plug **B** before charging the battery.
- For the recommended charge time and current, see the following table to avoid overcharging.

	Charge current (A)	Charge time (H)	Upper limit of fluid temperature (°C {°F})
Normal charge	$\frac{\text{Value of 5-hour rating capacity}}{10}$	$\frac{*\text{Amount of discharge (Ah)}}{\text{Charge current (A)}} \times 1.2\text{(to 1.5)}$	45 {113}
Quick charge	$\frac{\text{Value of 5-hour rating capacity}}{1.5}$	0.5	45 {131}

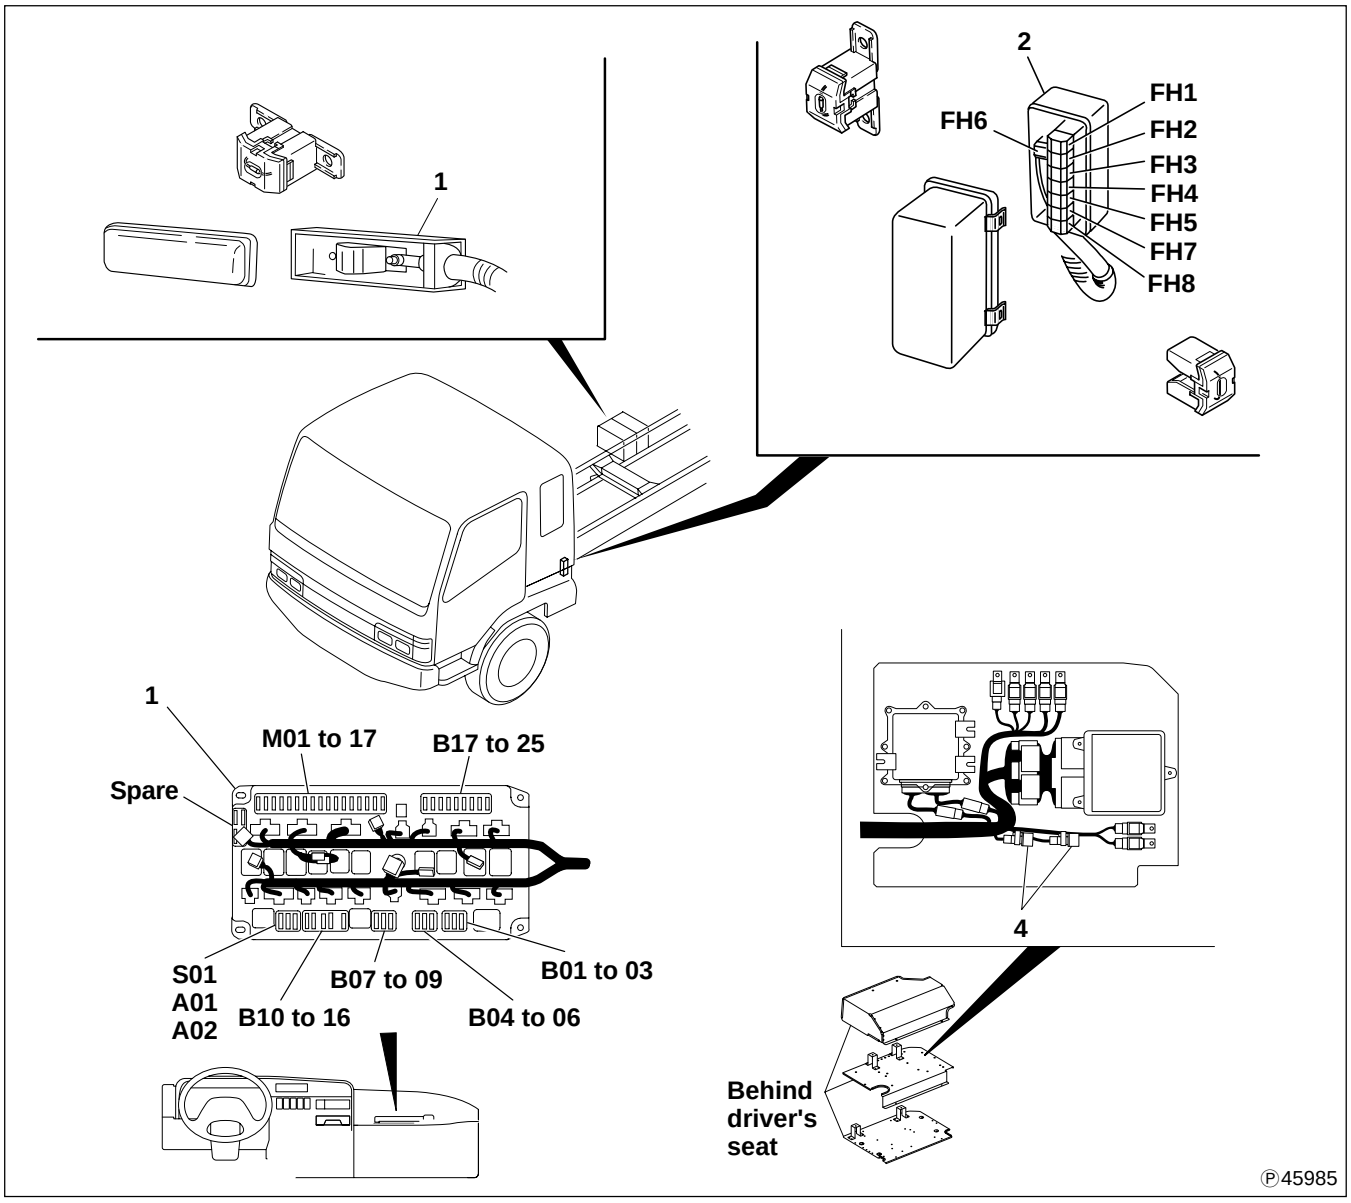
* Amount of discharge (Ah) = 5-hour rating capacity (Ah) × $\frac{\text{Amount of discharge (\%)}}{100}$

- Use the graph shown on the left to calculate the amount of discharge (%).
- Use diluted sulfuric acid, made up of sulfuric acid and refined or distilled water, as the battery electrolyte.
- The specific gravity of fully-charged battery electrolyte is 1.280 with the temperature at 20°C {68°F}.

DANGER⚠

- **Do not let the battery electrolyte level rise and overflow while charging the battery.**
- **Keep work lights away from the battery while charging it or it might explode.**
- **Be careful not to generate sparks while charging the battery because it is dangerous.**
- **After charging the battery, tighten vent plug B, wash away sulfuric acid from the battery using water, and dry the surface.**
- **Be sure to check the electrolyte level before charging the battery. Charging with the electrolyte level below the lower limit (LOWER LEVEL) can cause premature deterioration, heat generation and explosion of the battery.**

Fuse



1 Main high-current fuse
2 High-current fuse box
3 Relay and fuse box
4 Fuse holder

CAUTION ⚠

- **If a fuse blows, make sure you identify and remedy the cause, then replace the fuse.**
- **Make sure that you replace the fuse with one having the same rating.**
- **Make sure that you remove the ⊖ terminal of the battery cable before removing main high-current fuse 1 and high-current fuses FH1 to 8.**

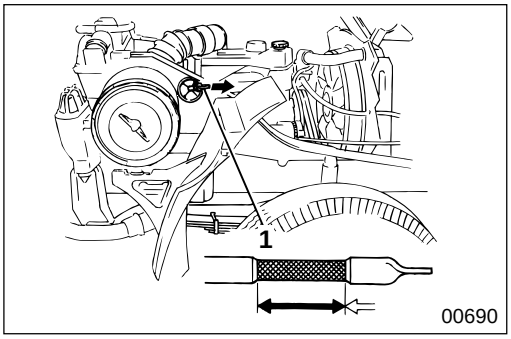
Engine Oil

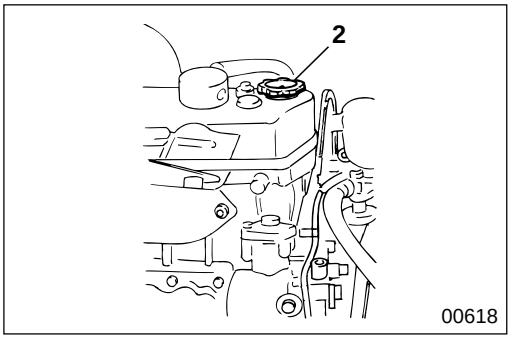
Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
3	Oil pan drain plug	69 {51, 7}	—



[Inspection]
- Pull out dipstick **1**, wipe off the oil with a cloth.
- Reinsert dipstick **1**, then pull it out carefully.
- Oil level is correct if there is oil sticking to dipstick **1** within the hatched area.
- If the level is low, top it up.
- Tilt the cab.

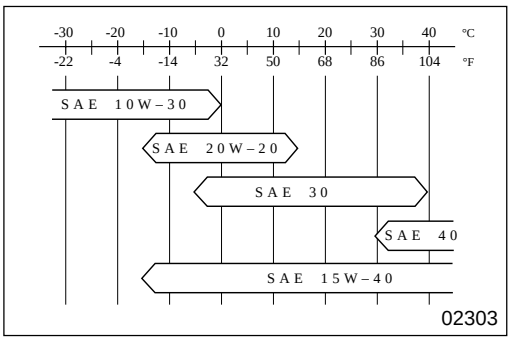


[Replenishment]
- Clean the area surrounding oil filler cap **2** and prevent dust from entering through the filler.
- Remove oil filler cap **2** and top up with engine oil.
- Wait five minutes before checking the oil level.
- Replace filler cap **2**.

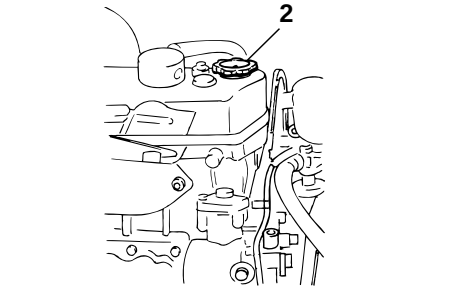
WARNING
- **Wipe up any engine oil that has been spilled because it can cause a fire.**
- **Do not touch the engine while it is hot because it will burn you.**

CAUTION

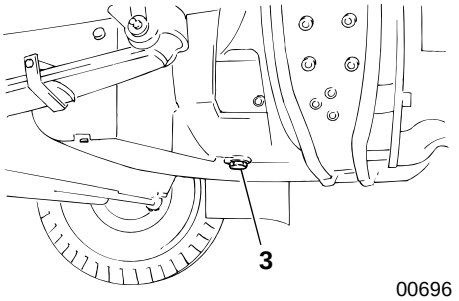
Take care not to spill engine oil on the V-bells, because this would cause them to slip, reducing service life.



[Replacement]
Since engine oil greatly influences the performance, the life expectancy, and the ability to start the engine, use only oil of the specified grade and viscosity.
The chart illustrates the relationship between oil viscosity and the ambient air temperature.



00618



00696

- Clean the area surrounding oil filler cap **2** and prevent dust from entering through the filler.
- Remove oil filler cap **2**.
- Remove oil pan drain plug **3**, and drain the oil. At the same time replace the oil filter.
- After reinstalling drain plug **3**, slowly add engine oil through the oil filler.
- Using the dipstick, check the oil level after more than six minutes have passed.
- Start the engine and let it idle. When the oil has reached all parts, stop the engine. Let 30 minutes pass before checking the oil level again.

Clutch Fluid (Brake Fluid)

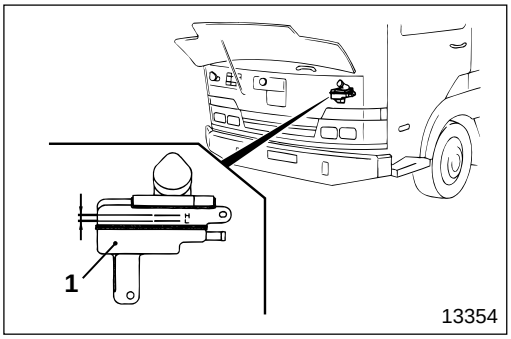
Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
2	Air bleeder (For air bleeding of clutch power cylinder)	25 to 34 {18 to 25, 2.5 to 3.5}	—

Fluid

Location	Points of application	Kinds	Quantity
1	Fluid tank	Brake fluid (SAE J1703f or FMVSS No.116 DOT3)	As required



CAUTION

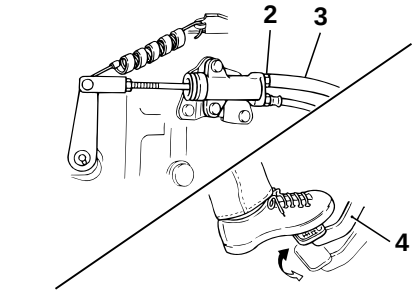
- **Be careful not to splash brake fluid on related parts as this could damage the paintwork.**
- **Be sure to wipe off brake fluid immediately if you splash it on the paintwork.**
- **You must use new brake fluid (SAE J1703f or FMVSS No.116 DOT3). Do not add different quality fluid or mineral oil (gas oil, engine oil, gear oil, automatic transmission fluid, etc.) to the clutch system, because this will cause the rubber parts of the clutch system to swell, resulting in faulty clutch operation.**
- **Do not allow foreign particles or water to become mixed into the brake fluid when refilling, because this will cause faulty clutch operation.**
- **If you use a mug for adding brake fluid, keep it solely for that purpose to prevent contamination from different quality fluids or mineral oils.**

[Inspection and replenishment]

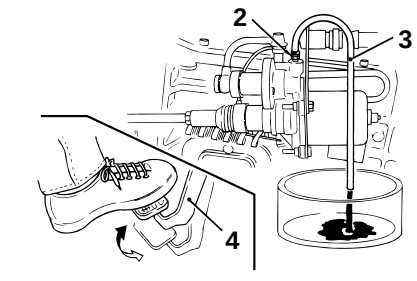
Inspect the level of the brake fluid in fluid tank **1**. It should fall between the "**H**" and "**L**" levels.

If it is below the "**L**" level, lift up the lid flap and remove the cap from fluid tank **1**, then supply the specified brake fluid until the level has come up to the "**H**" level. Do not fill above the "**H**" level.

< Except for FM657 (M8S2×5) >



< FM657 (M8S2×5) >



[Replacement]

- Attach vinyl pipe **3** to air bleeder **2** of the clutch power cylinder or the clutch booster.
- Loosen air bleeder **2** and depress clutch pedal 4 several times to drain brake fluid completely.
- Supply new brake fluid to the "**H**" level of fluid tank **1**. Depress clutch pedal **4** repeatedly until the old brake fluid discharged from vinyl pipe **3** is replaced by the new brake fluid.

< Except for FM657 (M8S2×5) >

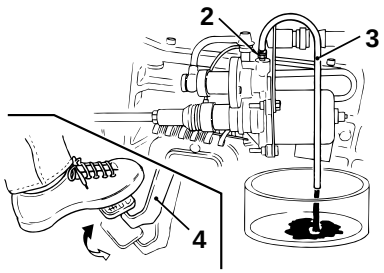
< FM657 (M8S2×5) >



13429

[Air bleeding]

NOTE

Carry out this operation maintaining the brake fluid level in fluid tank 1 between "H" and "L".

- Attach vinyl pipe **3** to air bleeder **2** of the clutch power cylinder or the clutch booster as in the replacement procedure.
- Fill fluid tank **1** with brake fluid, and loosen air bleeder **2** of the clutch power cylinder or the clutch booster, then depress clutch pedal **4** continuously.
- Keep depressing clutch pedal **4**, and tighten air bleeder **2** when air is bled completely.
- Depress clutch pedal **4** several times again, then keep it depressed at its fullest extent.
- With clutch pedal **4** depressed, loosen air bleeder **2** to drain brake fluid containing air. Release the pedal after tightening the air bleeder.
- Repeat this operation until air is no longer present in the fluid being drained.
- When this operation is completed, tighten air bleeder **2** at specified torque.
- Check that brake fluid is at the "**H**" level of fluid tank **1**, and supply new brake fluid if necessary.
- Check for brake fluid leakage from each of the parts with clutch pedal **4** depressed.

[Inspection and replenishment]

- Remove inspection plug **1** and check whether the oil level is up to the edge of the entrance.
- If the level is low, add oil through the inspection plug hole until the level comes up to the edge of the entrance.

[Replacement]

- Drain the oil after removing inspection plug **1** and drain plug **2**.
- Remove any metal particles sticking to the magnetic part of drain plug **2** before reinstalling the plug.
- Add oil through the inspection plug hole until the level comes up to the edge of the entrance.
- Reinstall inspection plug **1**.

[Inspection and replenishment]

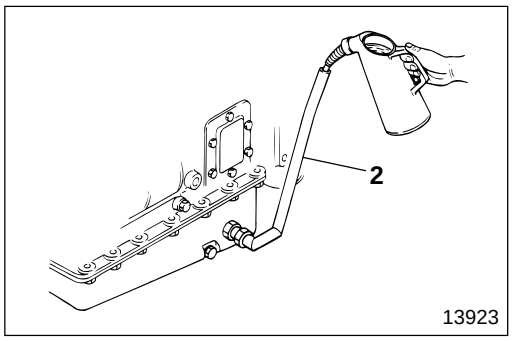
- Park the vehicle on level ground, make sure that the parking brake is fully activated and chock the wheels to keep them from rolling.
- Start the engine and let it idle. To fill the hydraulic circuit with automatic transmission fluid, shift the range selector lever from N → R → N → D → 2 → D → N. Repeat this process five times, finally shifting to N.
- While the engine is still idling, pull out dipstick **1** and wipe off the fluid sticking to it. Reinsert the dipstick, then pull it out again and check the fluid level.
- If the fluid level is inspected right after the engine is started and the fluid temperature is still low (approximately 15 to 49°C {60 to 120°F}), the level should be within area **A** marked COLD on dipstick **1**.
- If the fluid level is inspected after the vehicle has been driven and the fluid temperature is high (approximately 71 to 93°C {160 to 200°F}), the level should be within area **B** marked HOT on dipstick **1**.

WARNING

Take care during the inspection because the engine will be running. Take sufficient care to avoid burns or injuries resulting from contact with moving parts.

NOTE

- **Make sure the vehicle is parked on level ground when you are checking the fluid level.**
- **Make sure the selector lever is in the N position and the engine is idling when you are checking the fluid level. When the engine is stopped, the fluid level appears higher than it actually is.**
- **Be sure to wipe off the dust from the safety cap and the upper part of dipstick guide 2 before you pull out dipstick 1.**
- **To ensure the fluid is correct, reinspect the fluid level after an actual drive.**



13923

- If the fluid level is low, add automatic transmission fluid (DEXRON or DEXRON II type) through dipstick guide **2** until the correct level on dipstick **1** is reached.

[Replacement]

- Park the vehicle on level ground, chock the wheels and shift the range selector lever to the N position.
- Place a container under oil pan **3**, remove drain plug **4** and drain the fluid.

WARNING⚠

Take care because the fluid temperature immediately after the engine has stopped is very high. To avoid scalds, wait until a safe temperature has been reached before draining the fluid.

NOTE

- **The fluid will drain faster if the engine is first run to raise the fluid temperature.**
- **The fluid cannot be drained from the hydraulic circuit, the torque converter or the oil cooler.**
- **Check the drained fluid for dirt, metal particles and metal fragments.**

< FK >

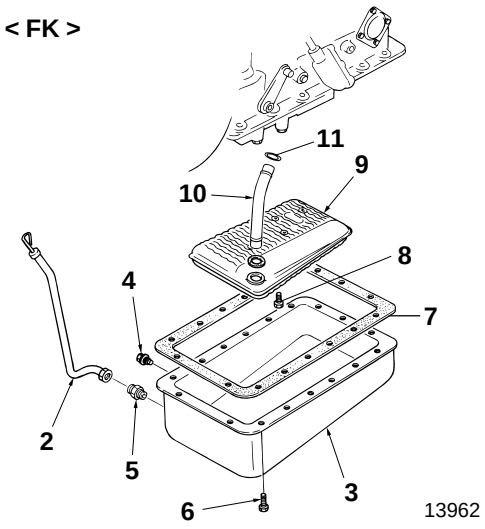
13922

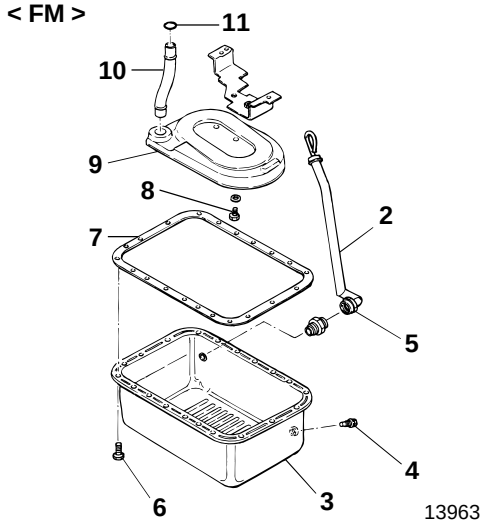
- Remove oil pan **3**, intake pipe **10**, O-ring **11**, gasket **7** and oil filter **9**.
- Clean oil pan **3**.
- Replace O-ring **11**, gasket **7** and oil filter **9**.

< FK >

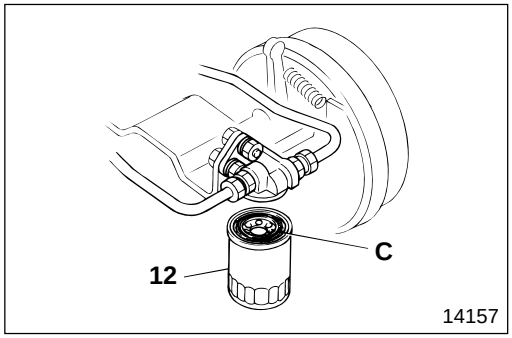


13962

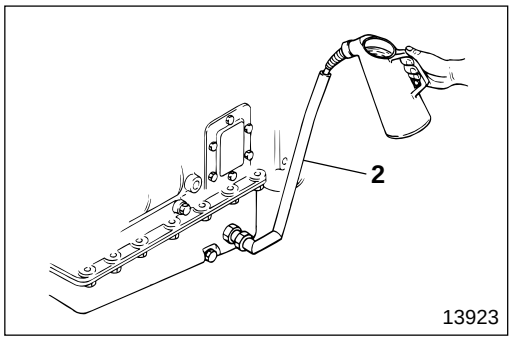
< FM >



13963



- Remove oil filter **12** (for oil cooler) by turning it counterclockwise.
- Lightly coat gasket **C** with the fluid before installing oil filter **12**. Then tighten the oil filter.



- Supply fluid through dipstick guide **2**.

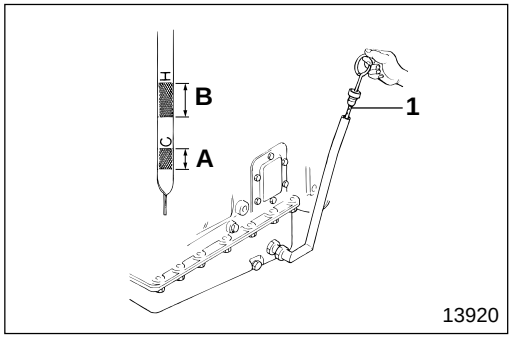
CAUTION

Make sure that dirt and foreign particles do not become mixed in with the fluid when it is added.

- Shift the range selector lever to the N position, start the engine and let it idle for about one minute.
- After shifting the lever through all positions once, shift it back to N position.

CAUTION

To prevent burning out the interior of the automatic transmission assembly, make sure that the engine is not allowed to race when you do the above.



- Check and adjust so that the fluid level is within the specified area on dipstick **1**.

NOTE

- **As the temperature of the fluid rises, so does the fluid level. If you add fluid while the temperature is still low (approximately 15 to 49°C {60 to 120°F}), make sure that the level stays within area A, marked COLD on dipstick 1.**
- **Let the engine idle and, while paying attention to the fluid level, pour in the fluid slowly.**
- **It is sometimes hard to check the fluid level, immediately after supplying fluid, because of the fluid adhering to the interior of dipstick guide 2. If this is the case, check the fluid level several times at intervals.**
- **Be careful not to supply too much fluid because you might mistake the fluid that overflows from the air breather for fluid leakage.**

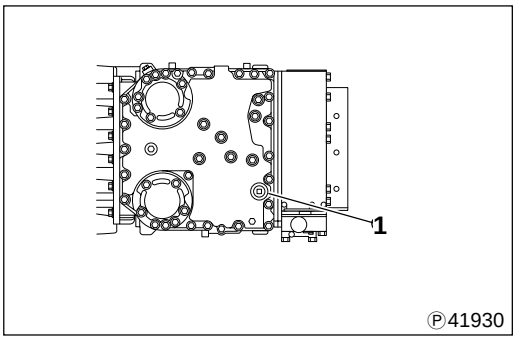
Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
—	Drain plug	25 to 32 {18 to 24, 2.6 to 3.3}	—



[Replacement of automatic transmission fluid]

(1) Draining

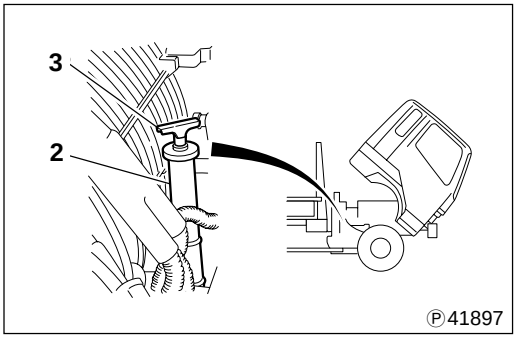
- Put the automatic transmission fluid drain pan under the transmission oil pan; then remove drain plug **1** behind the oil pan to drain automatic transmission fluid.

WARNING

Do not start any work for engine immediately after the engine is shut down. Wait until the engine cools to a safe temperature since a hot engine can cause burns.

NOTE

- **The draining can be performed more quickly by warming automatic transmission fluid to the operating temperature.**
- **It is impossible to drain automatic transmission fluid from the internal hydraulic circuit, the torque converter, or the oil cooler without disassembling the unit completely.**
- **Check for dirt in the drained automatic transmission fluid, and for existence of metallic powder or metal pieces.**



(2) Filling

- Prepare DEXRON III of 18 dm³ {18 L} (19 qts).
- Install oil pan drain plug **1** and tighten to specs.
- Fill with automatic transmission fluid through the filter tube **2**.

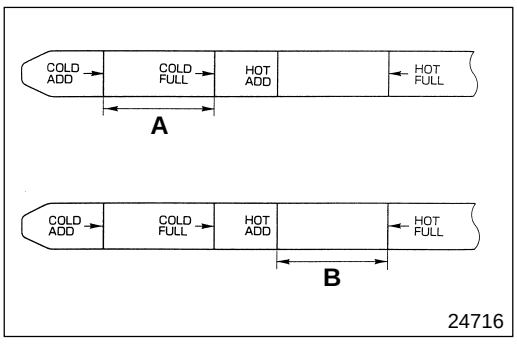
CAUTION

Be careful during filling so that dust or foreign particles do not enter.

- After starting the engine, run at idle RPM for approximately one (1) minute with the range selector to "N" position.
- After moving the range selector to each range, place it to "N" position again.

CAUTION

In this process, run engine at idle speed only — avoid running the engine at higher speeds.



- Add automatic transmission fluid until it reaches the low position of the specified range of dipstick **3**. Then, check the level of automatic transmission fluid. The level of automatic transmission fluid must be within the specified range of the dipstick.
  A: When temperature is low; 15 to 50°C {59 to 122°F}
  B: When temperature is high; 70 to 95°C {158 to 203°F}

NOTE

- **After filling the automatic transmission fluid, it may be difficult to see the level of automatic transmission fluid easily due to the automatic transmission fluid adhering to the inner wall of filler tube 2; therefore, recheck it after a short time.**
- **If the automatic transmission fluid is overfull, the automatic transmission fluid will overflow from the air breather. This might be misunderstood to be an automatic transmission fluid leak.**
- **Fill automatic transmission fluid gradually with letting the engine idle while paying a careful attention to the level of automatic transmission fluid.**

WARNING

The oil temperature is high immediately after the vehicle has stopped, so take care not to scald yourself.

- Remove inspection plug **1**, check the oil level and make sure it is up to the edge of the entrance.
- If the oil level is low, add oil through the inspection plug hole until the level comes up to the edge of the entrance.
- Insert inspection plug **1**.

[Replacement]

- Drain the oil after removing inspection plug **1** and drain plug **2**.
- Remove any metal particles sticking to the magnetic part of drain plug **2** before reinstalling the plug.
- Supply oil through the inspection plug hole until the level comes up to the edge of the entrance.
- Reinstall the inspection plug.

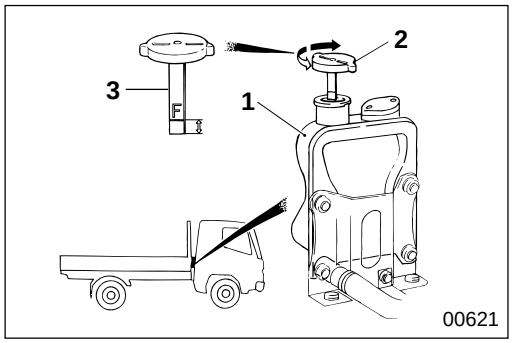
Fluid

Location	Points of application	Kinds	Quantity
1	Power steering oil tank	Automatic transmission fluid (DEXRON or DEXRON II type)	Between end and "**F**" on filler cap dipstick



[Inspection and replenishment]

- Straighten the front wheels and stop the engine.
- Remove filler cap **2** of power steering oil tank **1** by turning the filler cap counterclockwise.
- Wipe off the fluid sticking to dipstick **3** on filler cap **2**. Replace the filler cap.

NOTE

Check the fluid level without screwing on filler cap 2.

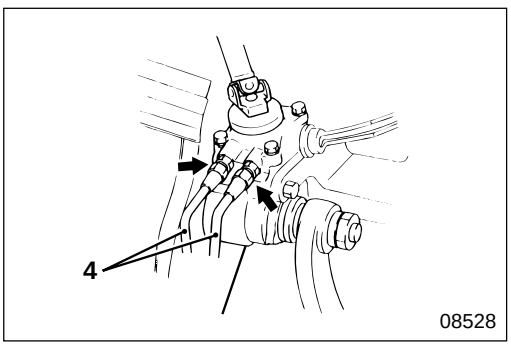
- Carefully lit up filler cap **2** and check the fluid sticking to dipstick **3** to make sure that the fluid is at a point between the end and "**F**" on the dipstick. If the level is low, add fluid.
- After inspection install filler cap **2** by turning it clockwise.

WARNING⚠

Close filler cap 2 firmly; otherwise power steering fluid will leak and could catch fire. Also wipe up spilled fluid.

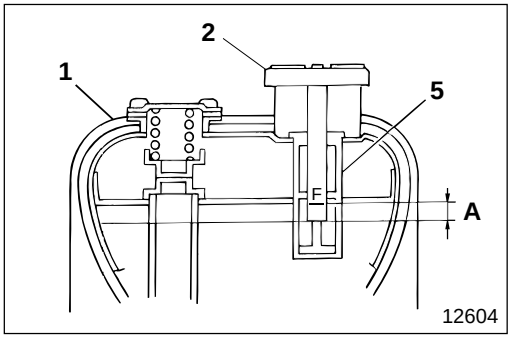
CAUTION⚠

If the fluid level is far below the recommended range, the fluid may be leaking.



[Replacement]

- Draining procedure
  - Jack up the front wheels.
  - Disconnect oil pipe **4** connected to the power steering booster.
  - Turn the steering wheel fully left and right repeatedly, and drain the fluid from the power steering booster.
  - After draining the fluid, tighten oil pipe **4** at specified torque.



- Refilling procedure
  - Pour fluid into power steering oil tank **1** up to the inner port of strainer **5**.
  - With the engine stopped, jack up the front wheels and turn the steering wheel fully left and right repeatedly. When the fluid level has dropped, add fluid to maintain the fluid level within range **A**.

NOTE

Check the fluid level without screwing on filler cap 2.

- Start the engine and letting it idle, turn the steering wheel fully left and right repeatedly. When the fluid level has dropped, add fluid to maintain the fluid level within range **A**. Repeat these steps until the fluid level does not drop.
- If there is an abnormal noise, air is still in the system. Turn the steering wheel several times to raise the fluid temperature to approximately 60 to 80°C {140 to 176°F}, then stop the engine and wait for approximately five minutes.
- Lower the front wheels and turn the steering wheel several times. If there is no noise, bleeding is completed.
- When bleeding is finished, check fluid level of power steering oil tank **1**, and pipe and hose connections for fluid leakage.

Special tools

Unit : mm {in.}

Location	Tool name and shape	Part No.	Application
—	Vinyl hose 	MH033102 (Obtain Locally)	Air bleeding

WARNING

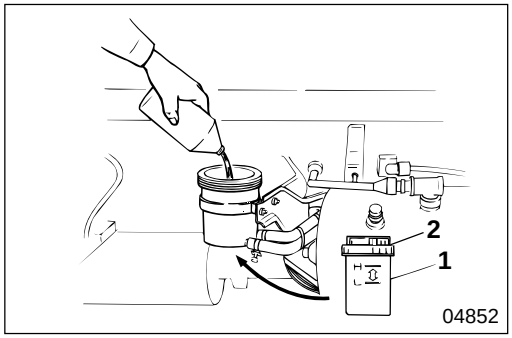
- **You must use new brake fluid (SAE J1703f or FMVSS No.116 DOT3).**
- **Do not add different quality fluid or mineral oil (gas oil, engine oil, gear oil, automatic transmission fluid, etc.) to the brake system, because this will cause the rubber parts of the brake system to swell, resulting in brake dragging or ineffective braking.**
- **Be sure not to allow dirt or water to become mixed into brake fluid when refilling, because this will cause the brake to malfunction.**
- **If you use a cup for adding brake fluid, keep it solely for that purpose to prevent contamination from different quality fluids or mineral oils.**

CAUTION

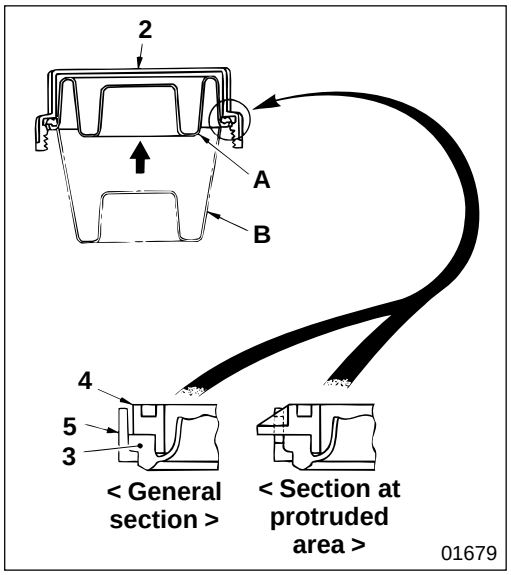
- **Be careful not to splash brake fluid on related parts as this could damage the paintwork.**
- **Be sure to wipe off brake fluid immediately if you splash it on the paintwork.**

NOTE

Supply brake fluid to maintain the "H" level of the brake fluid tank always.



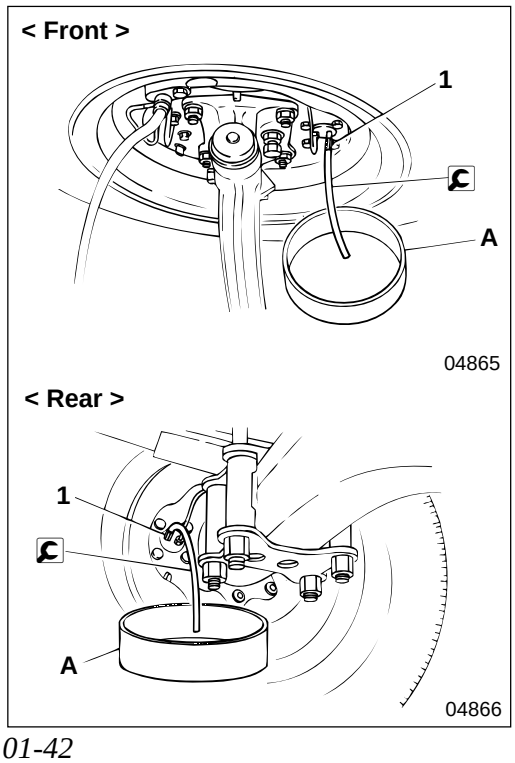
[Inspection and replenishment]
Inspect the level of the brake fluid in fluid tank **1**. It should fall between the "**L**" and "**H**" levels. If it is below the "**L**" level, remove cap **2** from the fluid tank, then supply the specified brake fluid until the level comes up to the "**H**" level. Do not fill above the "**H**" level.



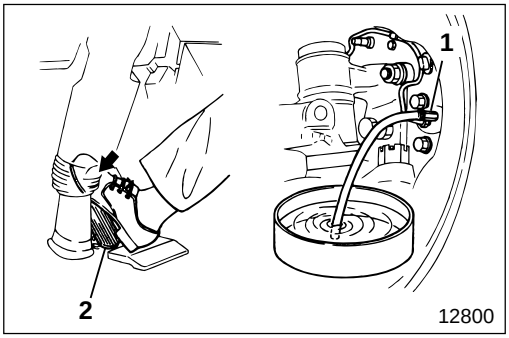
- If diaphragm **3** is not in its normal position when the brake fluid is supplied, correct it to its normal position, and install cap **2**. If brake fluid leaks from the cap area after you have supplied brake fluid, check whether the diaphragm is assembled as illustrated.

  4 : Slide ring
  5 : Ring cover
  A : Correct condition of diaphragm when brake fluid is being supplied
  B : Condition when diaphragm is extended when brake fluid has decreased

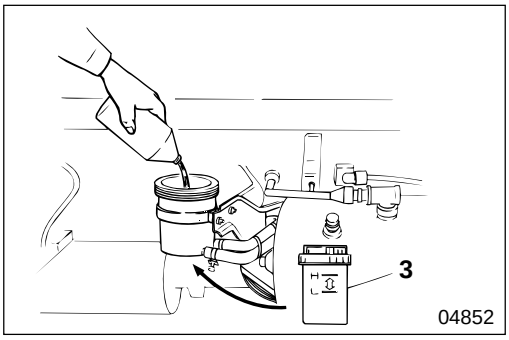
[Replacement]
- Start engine and let it idle during the brake fluid replacement procedure.



- Attach one end of vinyl hose to air bleeder **1** and place the other end in container **A**.

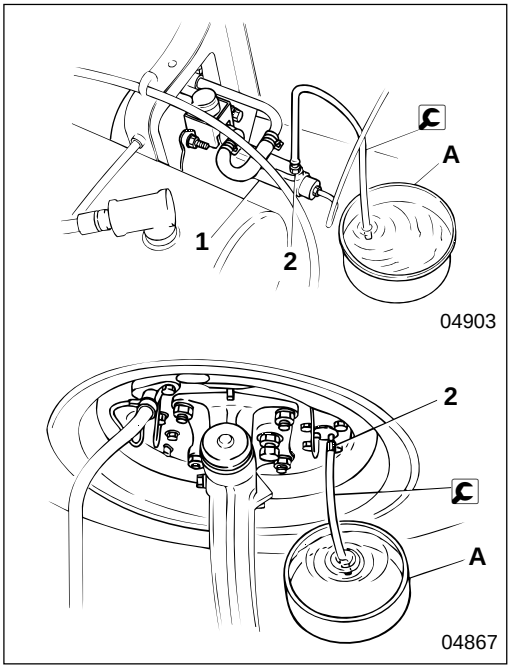


- Loosen air bleeder **1** and repeatedly depress brake pedal **2** to drain brake fluid completely.



- While maintaining a supply of new brake fluid up to the "**H**" level of fluid tank **3**, depress the brake pedal repeatedly until the old brake fluid of the brake system is replaced with new fluid.
- Carry out air bleeding of the brake system.

[Air bleeding]



- Start the engine and let it idle during the air bleeding procedure.
- Attach one end of 🔧 vinyl hose to front or rear airmaster **1**. Then, attach one end of another vinyl hose to air bleeder **2** of the wheel brake. Finally, place both open ends in container **A** filled with brake fluid.

- Carry out air bleeding in the following sequence:

Front brake system

Airmaster for front
↓
Right-hand side wheel brake
↓
Left-hand side wheel brake

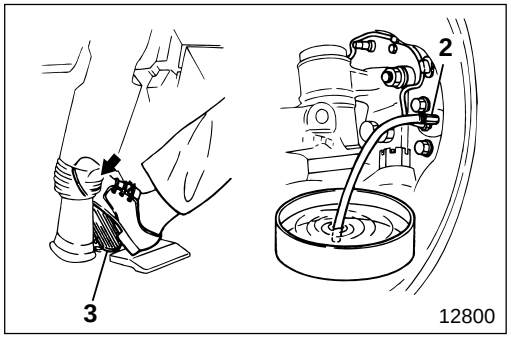
Rear brake system

< Right-hand side >

Airmaster for rear (right-hand side)
↓
Right-hand side wheel brake

< Left-hand side >

Airmaster for rear (left-hand side)
↓
Left-hand side wheel brake



- Depress brake pedal **3** slowly a few times, and with the brake pedal depressed, loosen air bleeder **2** to drain brake fluid containing air.

- Tighten air bleeder **2**, and release brake pedal **3**.
- Repeat this service procedure until air is no longer present in the fluid being drained.
- Tighten air bleeder **2** at specified torque as soon as brake fluid flowing out is free of air bubbles.

- Adjust brake shoe clearance when you have finished air bleeding.
- Check that brake fluid comes up to level "**H**" of fluid tank. If it does not, refill with new brake fluid.
- Depress brake pedal **3** a few times and check for any leakage of brake fluid, then test the brakes.
- When you test the brakes, if the brake fluid warning lamp within the meter cluster lights, it means that air has not been bled completely. Repeat air bleeding procedure.

Inspection of Engine Compression

Service standards

Location	Maintenance item		Standard value	Limit	Remedy
—	Engine Compression	Each cylinder (200 rpm)	2550 kPa {370 psi, 26 kgf/cm^2} (dry)	1960 kPa {285 psi, 20 kg/cm^2}	Inspect

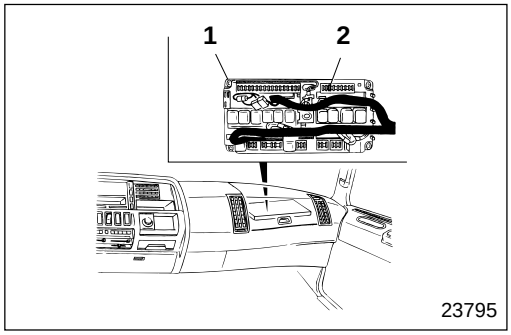
Special tools

Unit : mm {in.}

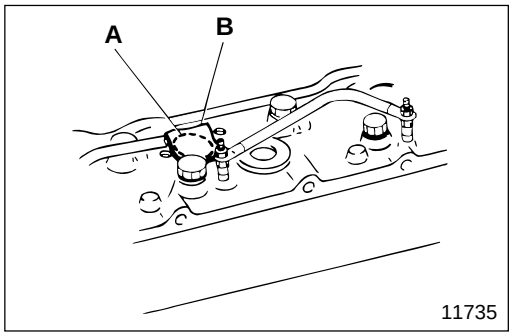
Location	Tool name and shape	Part No.	Application
—	Compression gauge adapter 	MH061461	Measurement of engine compression

A decrease of engine compression is a signal that it is time to overhaul the engine. It is strongly recommended that this item is inspected periodically and that you record the history of deterioration in engine performance as this will help you to diagnose causes of future irregularities.
When the vehicle is still new or immediately after installation of new parts, there may be a slight increase in engine compression, but normal values will be restored soon.

- Before inspection make sure that engine oil, starter and battery are in normal condition.
- Before inspecting the vehicle do the following:
  - Run the engine to bring the temperature of the coolant up to approximately 75 to 85°C {167 to 185°F}.
  - Turn all the lights and accessory equipment OFF.
  - Put transmission in neutral. (N range for automatic transmission)
  - Set the steering wheel at center and straight ahead position.



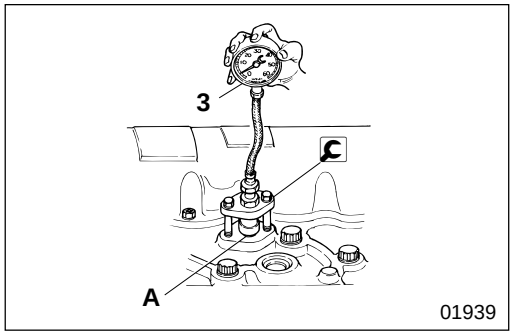
- Remove fuel-cut motor fuse **2** from fuse and relay box **1** in the driver's cab so that no injection of fuel takes place when cranking the engine using the starter.



- Remove all the injection nozzles. Gr 13
- Check that no foreign particles are sticking to waste cloth **B** covering injection nozzle mounting hole **A** after cranking the engine.

WARNING

You must stay clear of injection nozzle mounting hole A when you crank the engine during this inspection. Assume that all cylinders have cracked, and that coolant, engine oil, fuel, etc. have seeped into the cylinder chambers. If this is the state when the engine is cranked, there is an extreme danger of these substances being injected out of the injection nozzle mounting hole at high temperature.



- Install the nozzle gasket and compression gauge adaptor in injection nozzle mounting hole **A**, then attach compression gauge **3**.
- Measure engine compression while cranking the engine.
- Measure engine compression of each cylinder and calculate the difference between them.
- If the engine compression and pressure difference between each cylinder deviate from the limit, reinspect by pouring a small amount of engine oil into injection nozzle mounting hole **A**. Recheck compression.
  - If pressure increases : It is likely that either wear or damage of the piston ring and the cylinder sleeve surface has taken place.
  - If pressure remains low : It is likely that burning of the valve, faulty contact of valve surfaces and/or faults in the cylinder head gasket have developed.

Inspection and Adjustment of Valve Clearance

Service standards

Unit : mm {in.}

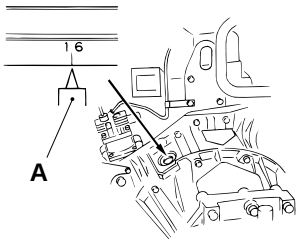
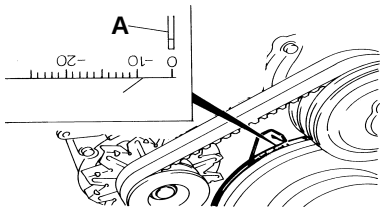
< Flywheel without PTO >



01940

< Flywheel with PTO >



14583

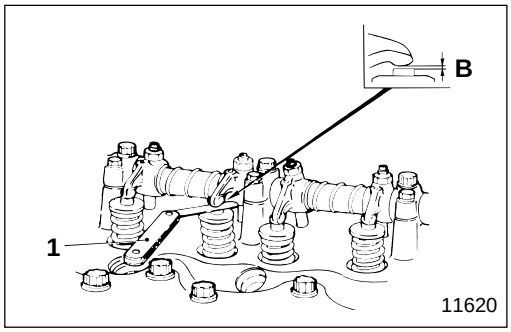
Inspect and adjust the valve clearance while the engine is cold in the following way.

[Inspection]

- Crank the engine to move No.1 or No.6 piston to top dead center of the compression stroke, aligning stamped mark "**1**", "**6**" on the flywheel with pointer **A** on the flywheel housing inspection window or aligning stamped mark on torsional damper with pointer **A**.

NOTE

The cylinder whose push rod is not pushing up the inlet/exhaust rocker is the one whose piston is at top dead center of the compression stroke.



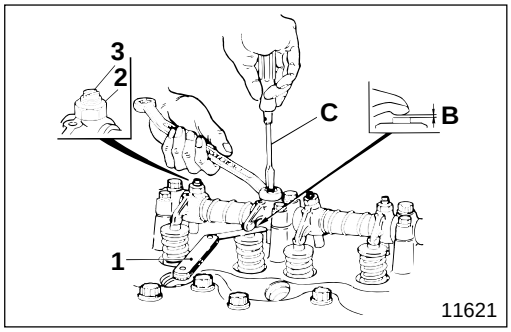
11620

- Measure valve clearance **B** when either No.1 or No.6 piston is at top dead center in accordance with the following table.
  x = adjust

Piston No.	1		2		3		4		5		6	
Valve arrangement	In-take	Ex-haust	In-take	Ex-haust	In-take	Ex-haust	In-take	Ex-haust	In-take	Ex-haust	In-take	Ex-haust
No.1 piston at top dead center	○	○	○	×	×	○	○	×	×	○	×	×
No.6 piston at top dead center	×	×	×	○	○	×	×	○	○	×	○	○

NOTE

Be sure when taking measurements using feeler gauge 1 that some resistance is felt when inserting the gauge. If the gauge can be inserted freely without any resistance, an accurate measurement cannot be obtained.



11621

- If the measured value deviates from the limit, adjust as follows:

[Adjustment]

- Adjust valve clearance **B** so that feeler gauge **1** encounters some resistance when it is inserted. Do this by loosening lock nut **2** and turning adjusting screw **3**.
- After adjusting, tighten adjusting screw **3** using screwdriver **C** and tighten lock nut **2**. Reinspect valve clearance **B** using feeler gauge **1**.

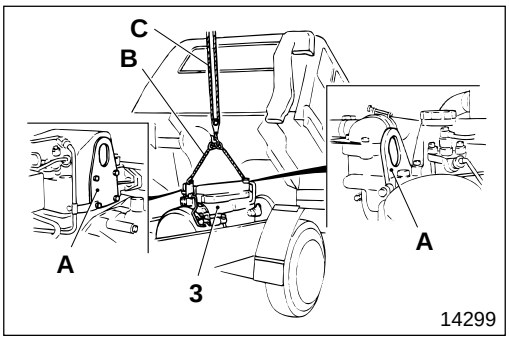
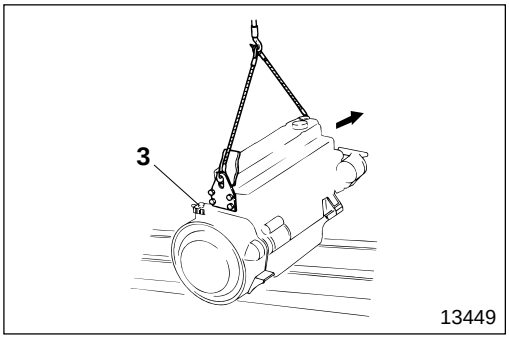
◆ Service procedure



3 Removal of engine assembly

- Hook lifting gear **B** to two hangers **A** on engine assembly **3** and lift the engine using crane **C** until the lifting gear becomes taut.
- Make sure that wiring and hoses are disconnected.



- Lower engine assembly **3** slowly so that it does not hit the frame or cab.

10 Cylinder head and valve assembly

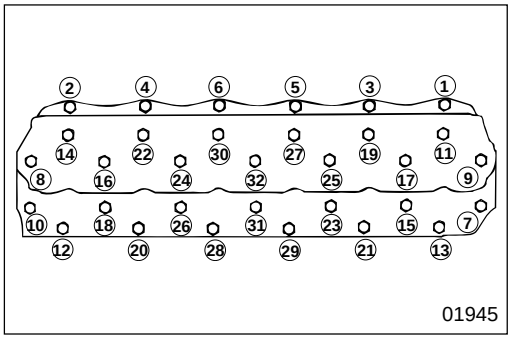
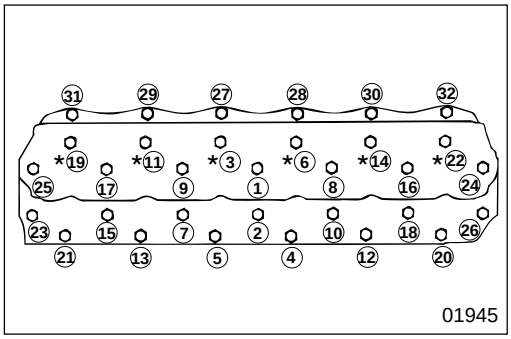
[Removal]

- Before removing cylinder head bolts **8**, first loosen adjusting screw **C** of rockers **A** that push down valve springs **B**.



01945

- Loosen cylinder head bolts **8** in the sequence as illustrated, then remove them.



01945

[Installation]

- Center punch the heads of cylinder head bolts **8** < M14 bolts > before each installation. Cylinder head bolts can be re-used a maximum of three times.

CAUTION⚠

If there are already three center-punch marks, replace the cylinder head bolt 8 with a new one.

- Lubricate m14 bolts with engine oil.
- After tightening cylinder head bolts **8** at specified torque (M14 bolt : 78 N·m {58 ft.lbs, 8 kgf·m}, M10 bolt : 17 N·m {13 ft.lbs, 1.75 kgf·m}) in sequence as illustrated, tighten further as follows:

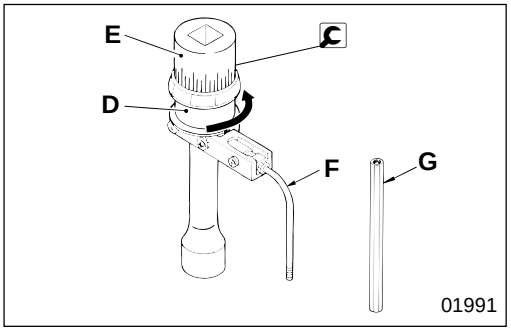
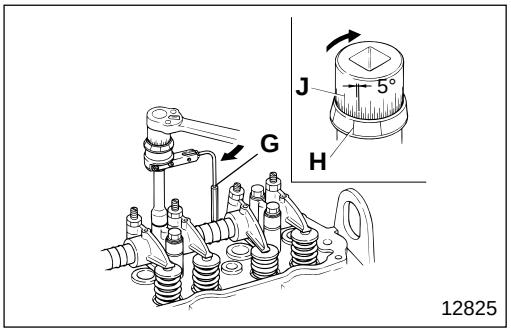
  ㉗ to ㉜ : M10 bolt additional 34 N·m {25 ft.lbs, 3.5 kgf·m}

***** :Tightened simultaneously with rocker and bracket assembly

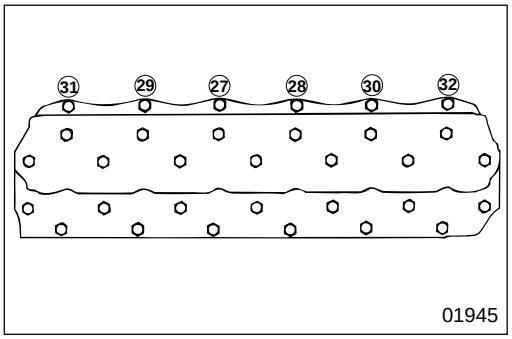


< M14 bolt >

- Using tool MH063388 turn socket wrench holder **D** counterclockwise and maintain spring tension in the wrench.
  E : Socket
  F : Rod
  G : Rod (for connection)



- Set socket wrench holder **D** so that extension rod **G** maintains contact against adjacent parts such as, rocker shaft bracket or the injection pipe.
- Select a scale that is convenient for reading graduation **H** on holder **D**.
- Tighten further by turning socket **H** clockwise by 180° (setting is in 5° increments), referring to graduation **J** on the selected scale.



< M10 bolt >

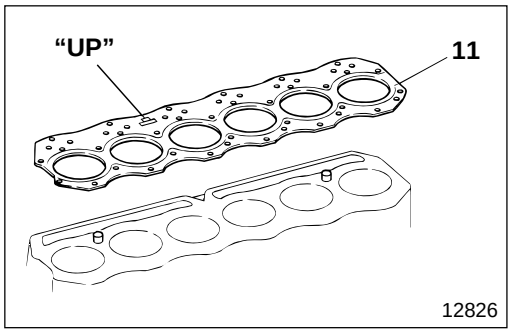
After tightening M14 bolts, tighten cylinder head bolts **8** (M10 bolt) at specified torque (34 N·m {25 ft.lbs, 3.5 kgf·m}) in the numbered order as illustrated.

11 **Cylinder head gasket**

[Removal]

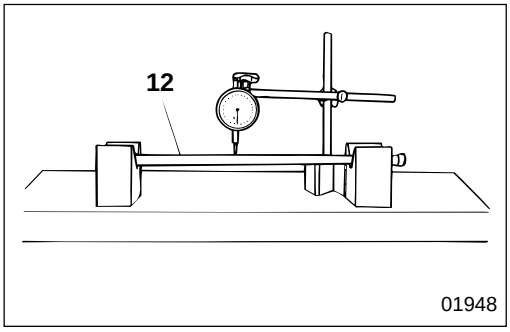
CAUTION

Be careful not to scratch the cylinder head or crankcase * when you remove cylinder head gasket 11.



[Installation]

- Install cylinder head gasket **11** onto crankcase * in the direction as illustrated.



12 **Push rod deflection**

If the measured value is higher than the limit, replace push rod **12**.

◆ Service procedure

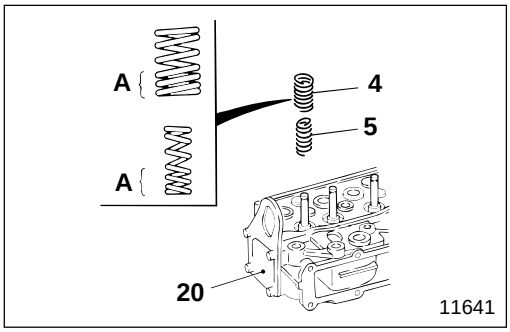
2 **Valve cotter**

[Removal]
Remove valve cotter **2** making sure that valve springs **4**, **5** are squarely and evenly pressed down by 🔧 valve lifter.

[Installation]
Follow the removal procedure in reverse.

CAUTION⚠

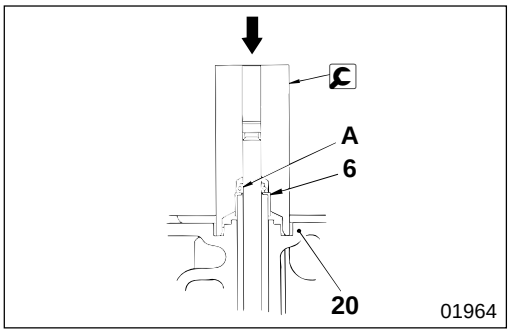
Be sure not to press down on valve springs 4, 5 too hard because this would cause upper retainer 3 to contact valve stem seal 6 and damage it.



4 **5** **Installation of outer and inner valve springs**

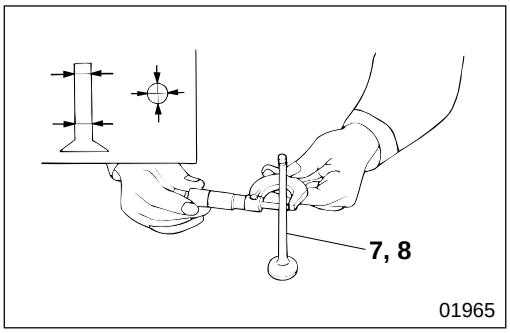
Install outer springs **4** and inner springs **5** in cylinder head **20** in the direction as illustrated.

A : Closely wound area



6 **Installation of valve stem seal**

- Apply engine oil to lip **A** of valve stem seal **6**.
- Tap down 🔧 valve stem seal installer until it hits cylinder head **20**.



7 **8** **Inlet valve and exhaust valve**

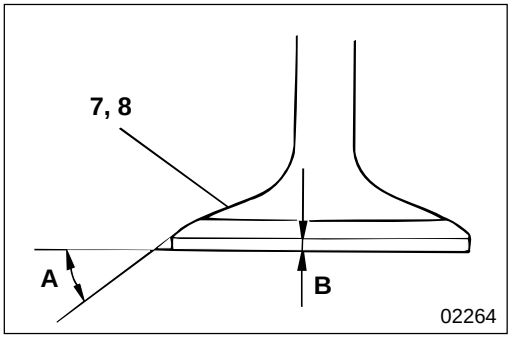
[Inspection]

(1) Inspection of stems

If the measured value is lower than the limit or in the case of excessive wear, replace valves **7**, **8**.

CAUTION⚠

Be sure to lap valve seats 17, 18 when valves 7, 8 are replaced with new ones. 🕮 **P11-25**

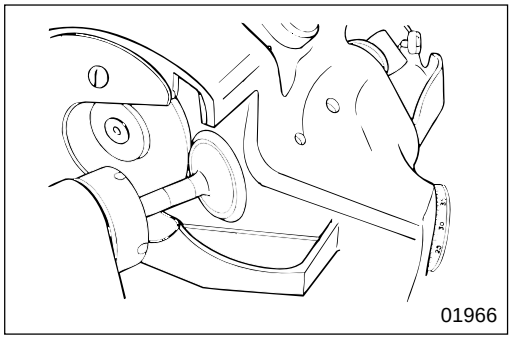


(2) Valve seat angle and valve margin

If the measured value is higher than the limit, correct or replace valves **7**, **8**.

A : Valve seat angle

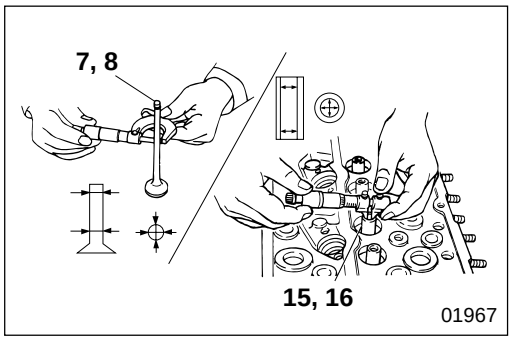
B : Valve margin



[Correction]

NOTE

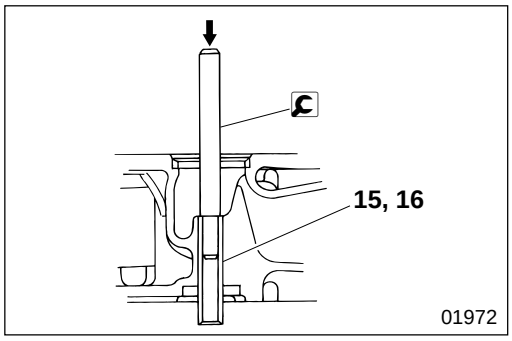
- **Be sure to keep the grinding work as light as possible.**
- **Be sure to replace valves 7, 8 after grinding if valve margin deviates from the limit.**
- **Be sure to lap valve 7, 8 and valve seats 17, 18 after grinding. P11-25**



7 **8** **15** **16** **Valve and valve guide**

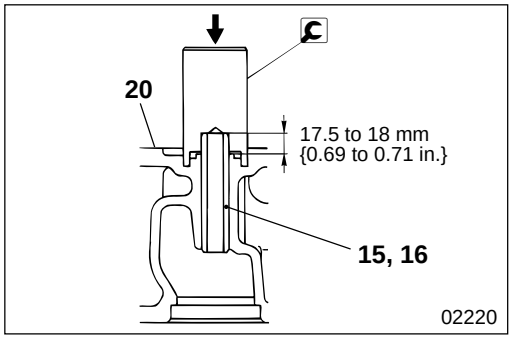
[Inspection]

When the clearance is higher than the limit, replace the faulty parts.



Valve guide

[Removal]

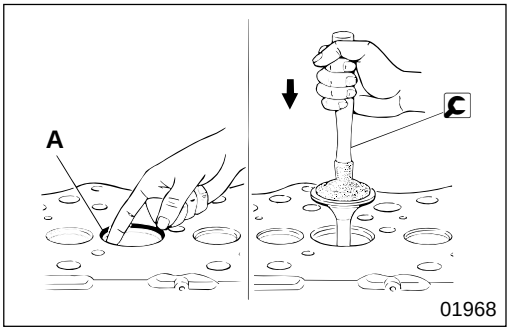


[Installation]

- Tap down valve guides **15**, **16** with 🔧 valve guide installer until it contacts cylinder head **20**.

CAUTION ⚠

- **The length of fit of valve guides 15, 16 is standardized. Be sure to use 🔧 valve guide installer.**
- **Be sure to distinguish between valve guides 15, 16. Exhaust valve guide 15 is longer.**



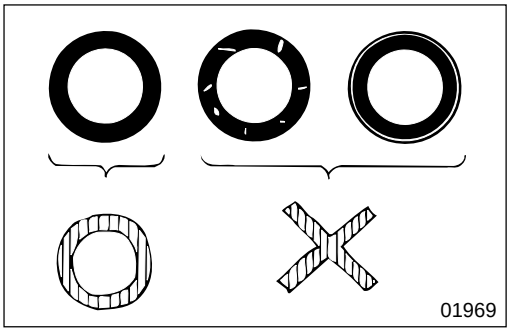
7 8 17 18 **Valve and valve seat**

[Inspection]

- Apply red lead evenly to entire surface **A** of valve seats **17**, **18** that contact valves **7**, **8**.
- Fit valves **7**, **8** to valve seats **17**, **18** and tap once without rotating.

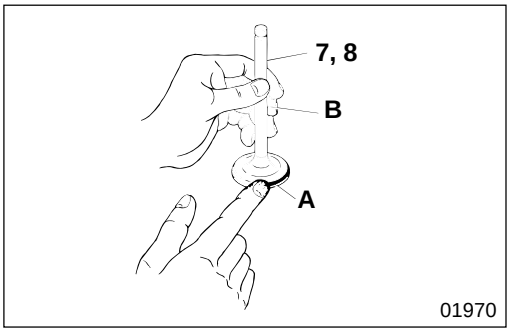
NOTE

Be sure to carry out inspection under the condition that valves 7, 8 and all parts of valve guides 15, 16 are normal.



- Check how much red lead has transferred to valves **7**, **8** to determine the contact of the valve and the seat. According to the degree of abnormality, take proper measures to correct it.

Contact conditions	Correction measures
Minor fault	Valve lapping
Major fault	Repair of valve and seat or replacement of both



[Correction]

Valve polishing is done in the following manner:

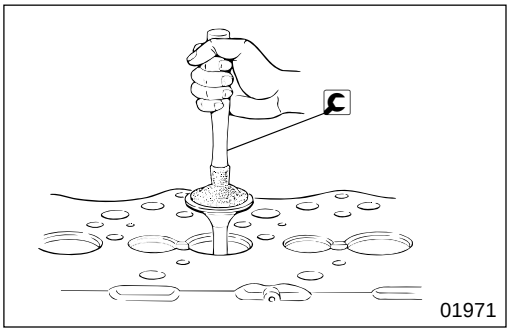
- Apply valve lapping compound thinly to contact surface **A** of valves **7**, **8** with valve seats **17**, **18**.

CAUTION ⚠

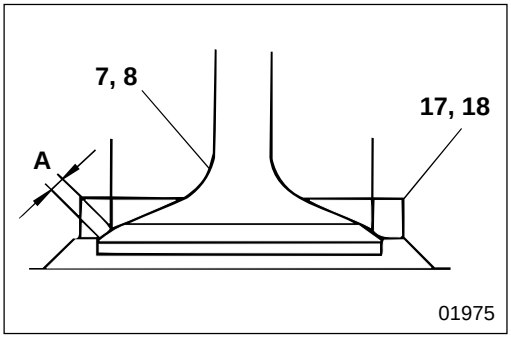
Take care not to smear stems B of valves 7, 8 with the compound.

NOTE

- **Start with medium grit compound (120 to 150 grit) and for finishing up, use finer grit (200 grit or finer).**
- **Mixing with a small amount of engine oil will make the compound consistent and make even application easier.**



- Tap valves **7**, **8** against valve seats **17**, **18** several times while rotating the valves slightly at each strike.
- Clean off the compound.
- Apply engine oil to contact surface **A** of valve seats **17**, **18** and smooth the surface.
- Check the contact of valves **7**, **8** and valve seats **17**, **18**.
- If contact does not take place completely around the seat, replace valve seats **17**, **18**.



17 **18** **Valve seat**

[Inspection]

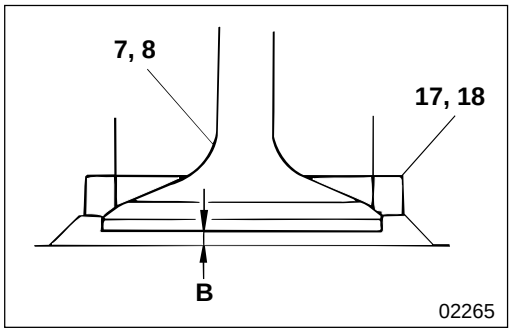
(1) Valve seat width

If the measured value is higher than the limit, replace valve seats **17**, **18**.

A : Valve seat width

NOTE

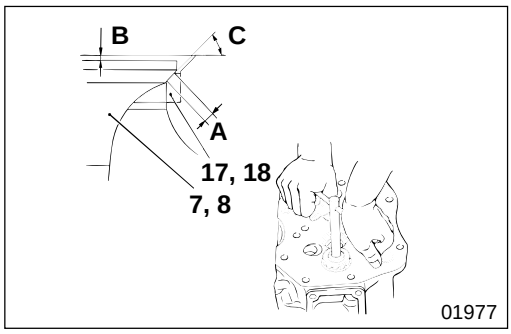
Be sure to lap and fit valves 7, 8 and valve seats 17, 18 after correction or replacement.



(2) Extent of valve recess from the bottom surface of cylinder head

If the measured value is higher than the limit, correct or replace the faulty parts.

B : Extent of valve recess



[Correction]

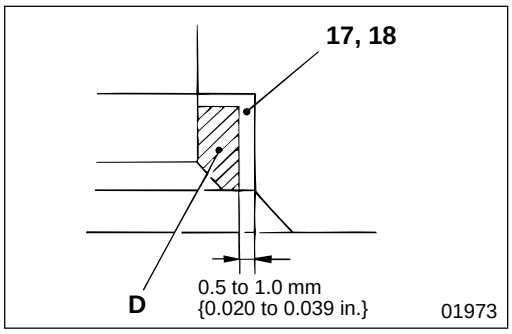
- Grind valve seats **17**, **18** using valve seat cutter or valve seat grinder.
- After grinding, do another light abrasion using 400 grit emery paper placed between the cutter and the seat.
- Adjust the seat width **A** of valves **7**, **8** using 15° or 75° cutter to make seat width conform to the standard value.

C : Valve seat angle

CAUTION ⚠

Be sure that as a result of grinding, recess B of valves 7, 8 does not become higher than the limit.

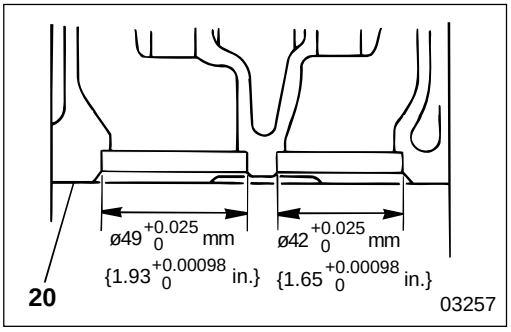
- After correction is done, be sure to carry out lapping and fitting on valves **7**, **8** and valve seats **17**, **18**.



[Removal]

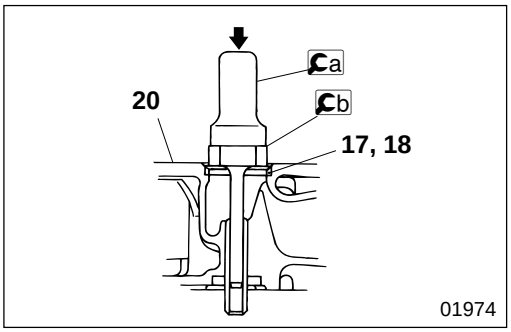
- Valve seats **17**, **18** have been set in by the cooling-off-process, and have to be thinned by grinding off the inner side for removal under normal temperature.

D : Part to be ground

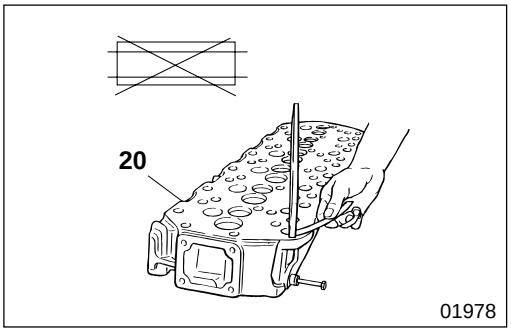


[Installation]

- Make sure that the diameter of valve seat hole of cylinder head **20** conforms to the standard value.
  E : Inlet valve seat hole diameter
  F : Exhaust valve seat hole diameter



- Immerse valve seats **17**, **18** in liquid nitrogen and cool them substantially. Press-fit into the cylinder head using Ca caulking tool body and Cb caulking rings inlet and exhaust.
- After installation of valve seats **17**, **18**, work until they contact valves **7**, **8** smoothly.



20 Inspection of cylinder head

Measure the extent of distortion of the bottom of cylinder head **20**, and if the measured value is higher than the standard value, grind using a surface grinder.

CAUTION

Be sure to keep the amount of grinding within the limit of the cylinder head thickness 20.

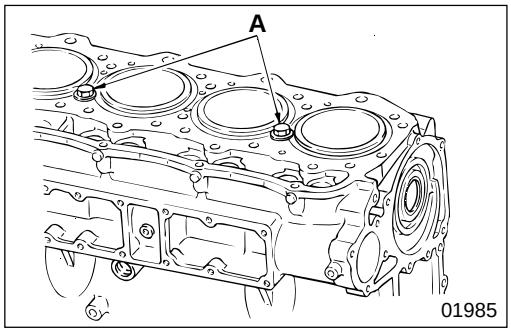
◆ Service procedure



● **Inspection before disassembly**

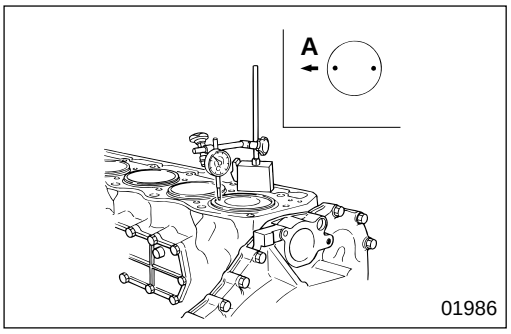
(1) Extent of piston protrusion from the upper surface of crankcase

NOTE

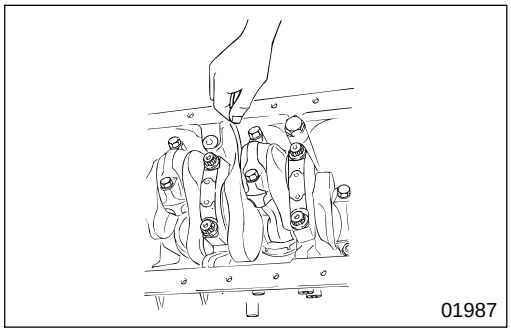
Always inspect the extent of piston protrusion because it affects the engine performance greatly.

WARNING⚠

Cylinder sleeves 6 might slip out beyond the top surface of the crankcase if the crankshaft is rotated. To avoid this, hold down the sleeves using bolts, tightened down with washers A at the cylinder sleeve flange.

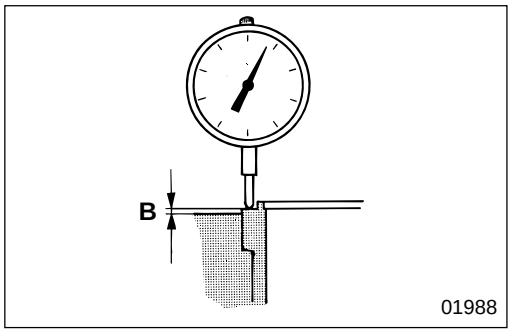


- Measure piston protrusion at two points on the top of the piston, and produce the average value.
  A : Front of the engine
- If the average value deviates from the limit, inspect clearance of the related parts.



(2) End play of connecting rod

- Measure the end play of each connecting rod.
- If the measured value is higher than the limit, replace the faulty parts.



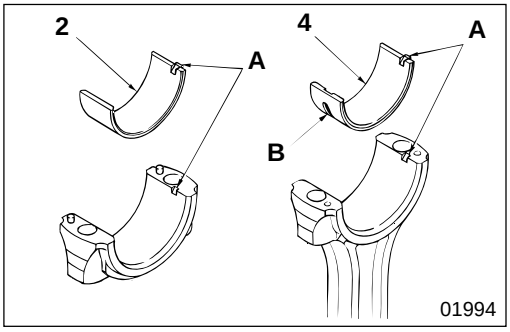
(3) Extent of cylinder sleeve flange area protrusion from the upper surface of crankcase

Replace cylinder sleeve **6** if the measured value deviates from the standard value.

B : Protrusion at cylinder sleeve flange area

CAUTION⚠

Unless the protrusion at the flange of cylinder sleeve 6 is adequate, contact pressure exerted upon the cylinder head gasket around the circumference of the cylinder sleeve will be low, and might cause leakage of combustion gases.



2 **4** **Connecting rod bearing**

[Installation]
Install connecting rod bearings **2**, **4** by matching lugs **A** to the connecting rods.

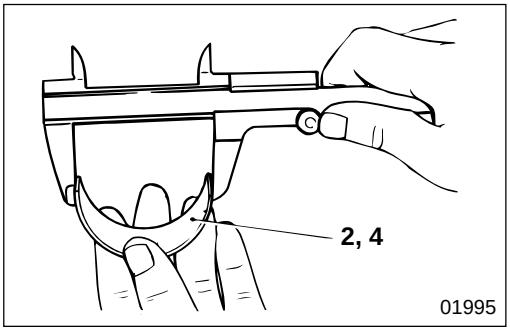
CAUTION

Be sure to distinguish between upper and lower connecting rod bearings 2, 4. The upper bearing has oil opening B while the lower bearing has no oil opening.

[Inspection]

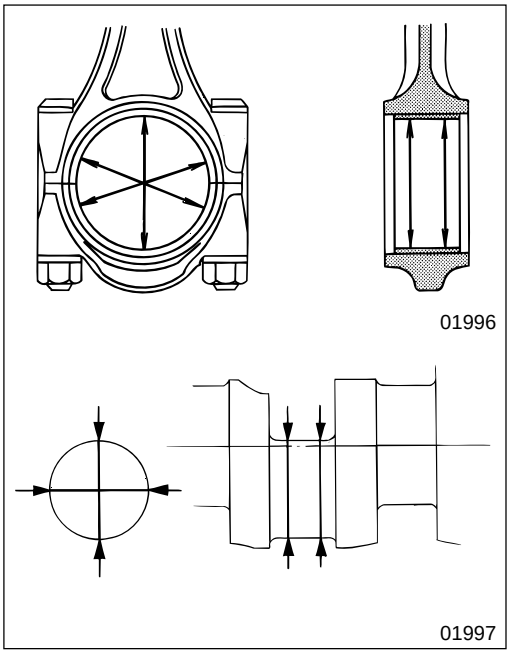
CAUTION

- **Do not forcibly open or expand connecting rod bearings 2, 4.**
- **When either upper or lower connecting rod bearings 2, 4 needs replacing, replace as a set.**



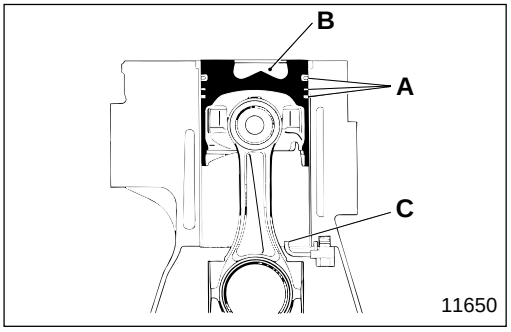
(1) Expansion at free state

If the measured value is lower than the limit, replace connecting rod bearings **2**, **4**.



(2) Clearance between connecting rod bearing and crankshaft

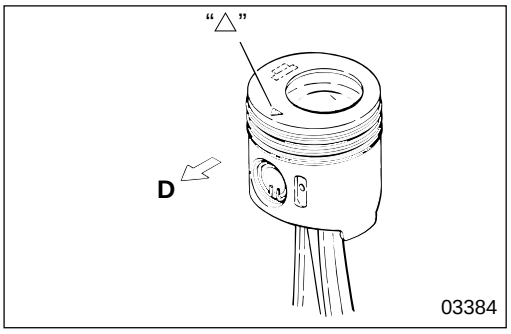
If the clearance between connecting rod bearing **2**, **4** and crankshaft is lower than the limit, replace the faulty parts.



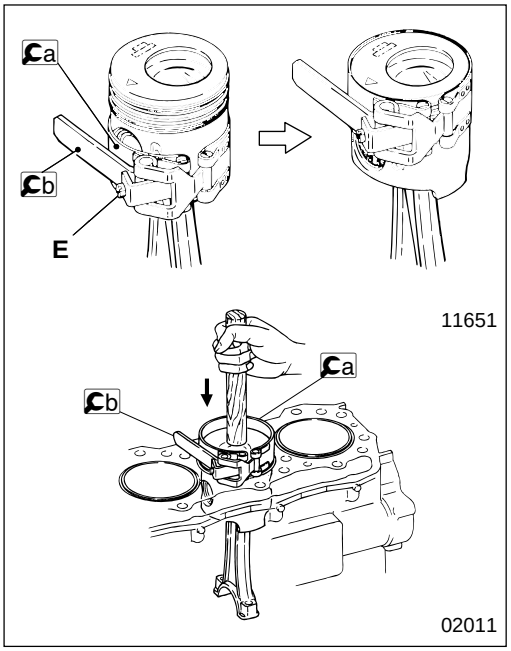
5 **Installation of piston and connecting rod assembly**

CAUTION

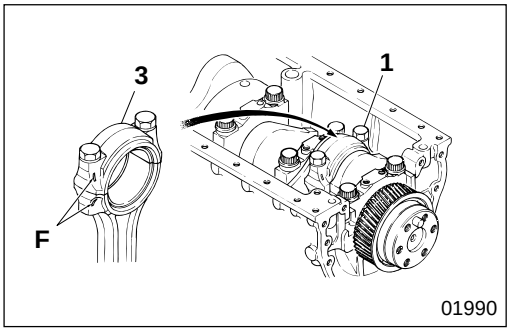
- **Be sure to fit piston ring A in the correct position.**
  P11-40
- **Be careful not to scratch or damage head B of the piston (a part of the combustion chamber).**
- **Make sure that the connecting rod does not hit oil jet C.**



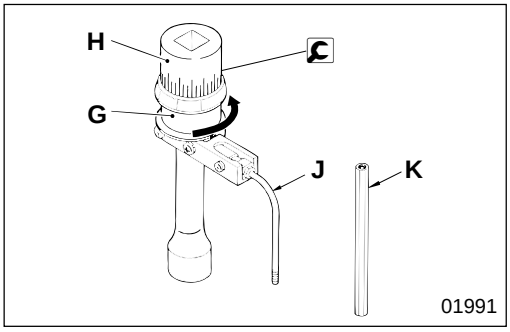
- Install piston front mark "△" directed towards the front of the engine using the following procedure.
  D : Front of the engine



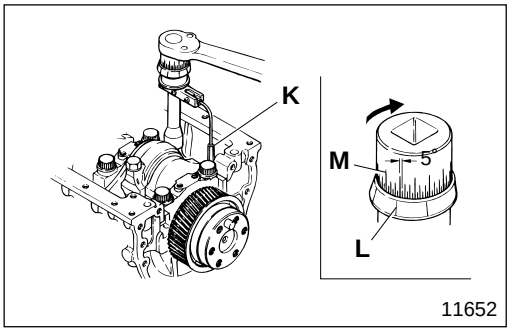
- Match the inner diameter of a piston guide clamp to the outer diameter of the piston skirt by turning adjusting bolt **E** of b piston guide lever.
- After adjusting, set a clamp and b lever at the top of the piston so that the clamp is flush with the top of the piston.



- After the piston is inserted, align alignment marks **F** on the connecting rod with the alignment marks on connecting rod cap **3** and tighten bolt **1** at specified torque. Then tighten the bolt further as follows:



- Turn socket wrench holder **G** counterclockwise and maintain spring tension in the wrench.
  H : Socket
  J : Rod
  K : Rod (for connection)

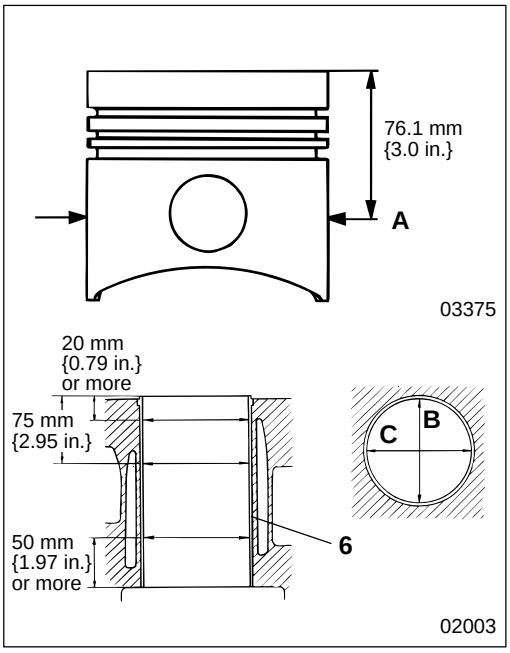


- Set the socket wrench holder **G** so that extension rod **K** maintains contact against the crankshaft.
- Select a scale that is convenient for reading graduation **L** on holder **G** side.
- Tighten further by turning socket **H** clockwise by 90°±5° (setting is in 5° increments) referring to graduation **M** using the selected scale.

NOTE

After installation of connecting rod cap 3, inspect the following points :

- **End play of the connecting rod : P11-30**
- **Piston protrusion : P11-30**



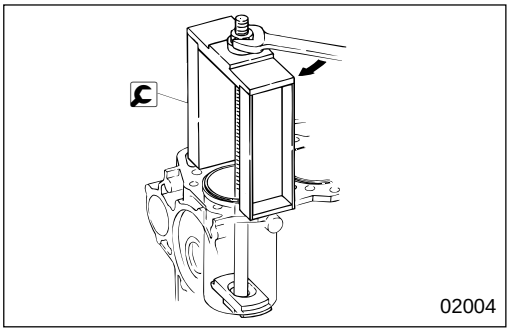
5 **6** **Piston and connecting rod assembly and cylinder sleeve**

[Inspection]
Replace the cylinder sleeve if the clearance deviates from the standard value. Mesure piston and sleeve as follows:

A : Position to measure the outer diameter of the piston
B : In the direction of the crankshaft axis (sleeve diameter - 3 places)
C : At right angles to the crankshaft axis (sleeve diameter - 3 places

NOTE

Cylinder sleeve 6 is a thin type so it is impossible to bore it out. Also, do not remove it except for replacement, because it is liable to become deformed when you remove it .



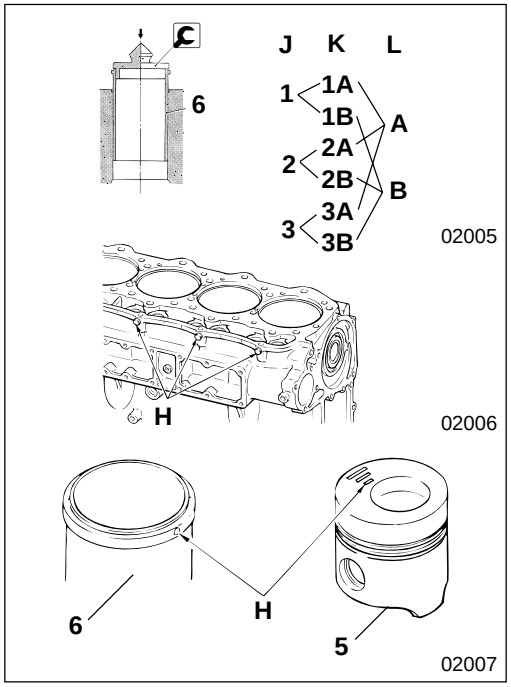
Cylinder sleeve

[Removal]

NOTE

If you are reusing cylinder sleeve 6, paint an alignment mark across the cylinder sleeve and the crankcase before removal so you can replace them in the same position.

PISTON, CONNECTING ROD AND CYLINDER SLEEVE



[Installation]
Apply engine oil to the outer surface of cylinder sleeve **6**, hold the entire upper part of [SST] cylinder sleeve installer in your hand evenly, and insert the cylinder sleeve slowly into the crankcase.

CAUTION

- **Use size marks H on cylinder sleeve 6, piston and connecting rod assembly 5, and the crankcase, as a reference when replacing the piston and sleeve.**
  - **J : Crankcase size mark**
  - **K : Cylinder sleeve size mark**
  - **L : Piston size mark**
- **Handle cylinder sleeve 6 with utmost care because it is thin; do not subject it to strong impact from a hammer, etc.**

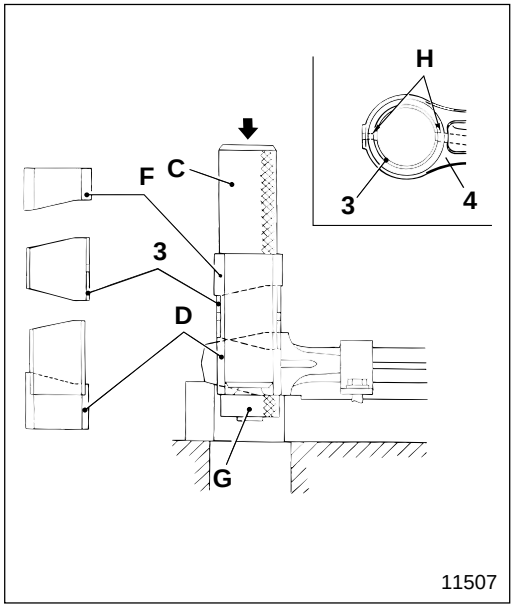
Connecting rod bushing

Use 🔧 connecting rod bushing puller kit to replace connecting rod bushing **3**.
(Components of 🔧 connecting rod bushing puller kit)
A : Base **B** : Bracket **C** : Puller **D** : Collar
E : Plate **F** : Collar **G** : Nut

[Pulling-out]

- Remove upper connecting rod bearing from the big end of connecting rod **4**.
- Place connecting rod **4** on base **A** and fix it to the base at two points, bracket **B** and plate **E**.
- Fit collar **D** in puller **C** in the direction as illustrated, and pull out connecting rod bushing **3** with a gradual load of approximately 49 kN {11020 lbf, 5000 kgf}.

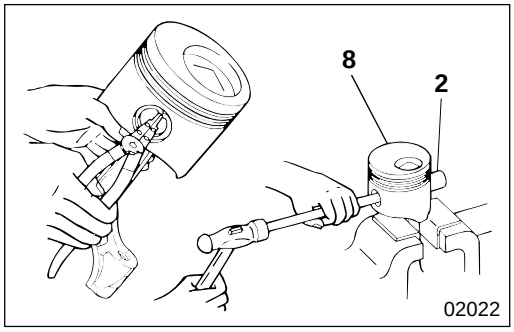


[Press-fitting]

- Apply engine oil to the exterior peripheral area of connecting rod bushing **3** and the inner area of the bushing fitting ring of connecting rod **4**.
- Fit collar **F**, connecting rod bushing **3** and collar **D** in puller **C** in the arrangement and direction as illustrated and mount them with nut **G**.
- Align oiling holes **H** of connecting rod bushing **3** and connecting rod **4**, and gradually press in the bushing with approximately 49 kN {11020 lbf, 5000 kgf} load.
- After press-fitting, ream connecting rod bushing **3** to make its clearance with piston pin **2** conform to the standard value.

NOTE

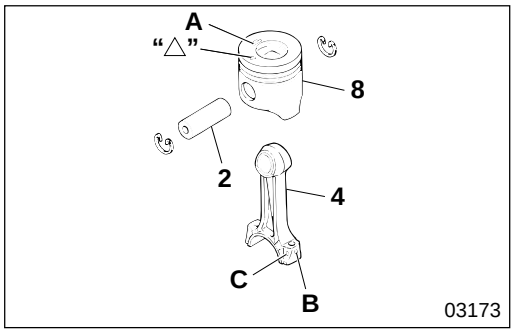
After press-fitting bushing 3, insert piston pin 2 and make sure that the rod moves smoothly without any excessive play.



2 4 8 Piston pin and connecting rod and piston

[Disassembly]

- Drive out piston pin **2** using a punch.
- When removal of piston pin **2** is difficult, warm piston **8** using a piston heater or hot water.

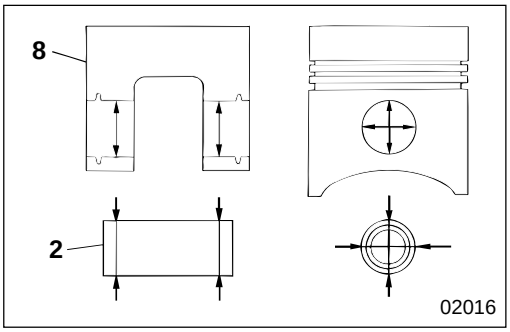


[Installation]

- Apply engine oil to piston pin **2** and assemble connecting rod **4** and piston **8** in the direction as illustrated.
  A : Piston mass (Mass of piston is marked)
  B : Connecting rod mass mark (Alphabetical : A, B, C, D, E, F, G, H, I, V, W, X, Y, or Z)
  C : Mounting base of connecting rod cap
  △ : Front mark
- When piston pin **2** insertion is difficult, warm piston **4** using a piston heater or hot water.

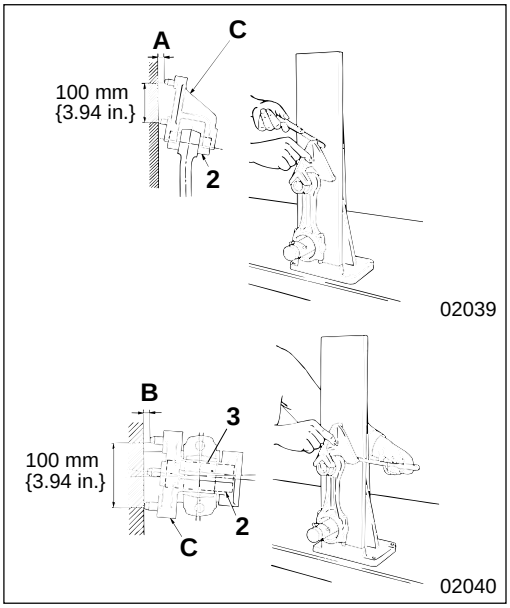
CAUTION⚠

- **Make sure that the total mass error of all pistons 8 in one engine is 10 g {0.35 oz} or less.**
- **Be sure to install connecting rods 4, to be used in one engine, that have identical mass mark B.**
- **Be sure that after inserting piston pin 2 the connecting rod operates smoothly without excessive play.**



2 **8** **Clearance between piston pin and piston**

If the clearance is higher than the limit, replace the faulty parts.



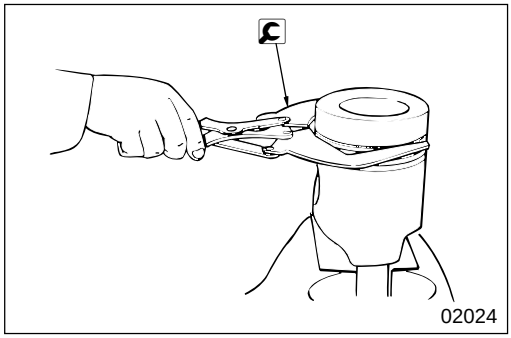
4 **Degree of bend or distortion of connecting rod**

- Mount connecting rod bushing **3** and piston pin **2** to connecting rod **4**.
- Measure degree of bend **A** and distortion **B** of connecting rod **4**. If the measured value is higher than the limit, repair or replace the connecting rod.
  C : Connecting rod aligner (Measuring instrument)

NOTE

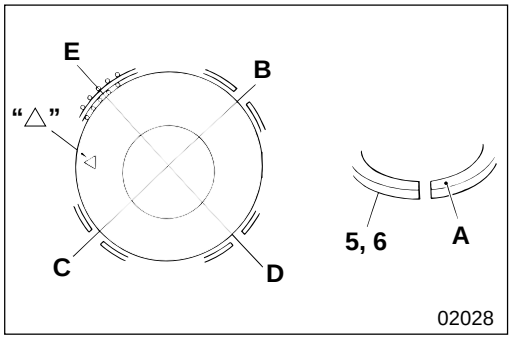
- **When making measurements by mounting connecting rod 4 to connecting rod aligner C, make sure that the upper connecting rod bearing and the lower connecting rod bearing are mounted on the rod.**
- **Mount the connecting rod cap by tightening the bolt at specified torque.** 🕮 **P11-28**

PISTON, CONNECTING ROD AND CYLINDER SLEEVE

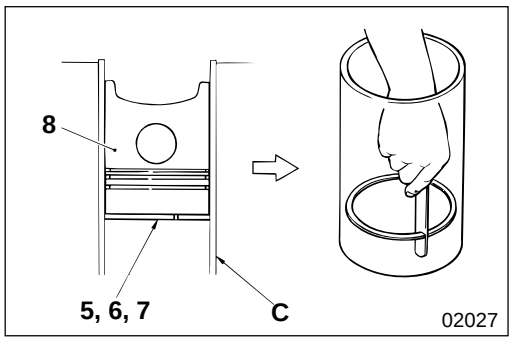


5 to 8 Piston ring and piston

Piston ring
[Removal]



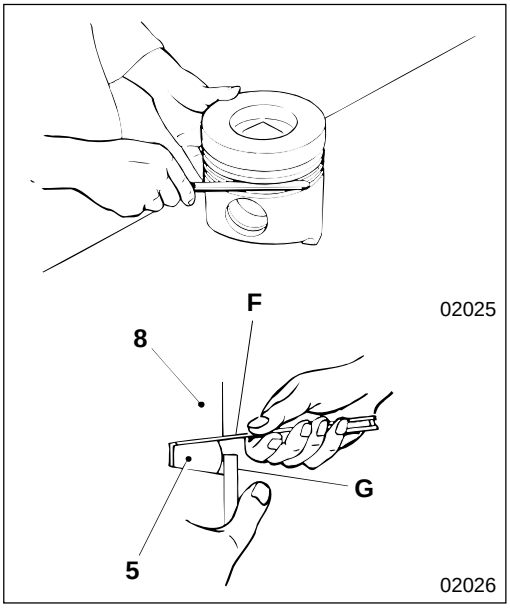
[Installation]
- Install oil ring **7** so that split **D** and the butting joint of expander spring **E** come to the points as illustrated.
- Compression rings **5** and **6** have a manufacturer's mark **A** at the split, and installation should be made with the mark upward.
  B : The split of the 1st compression ring
  C : The split of the 2nd compression ring
  D : Oil ring slit
  E : Oil ring expander spring butt joint
  △ : Front mark of piston



[Inspection]

(1) Piston ring gap
- Install piston rings **5** to **7** into the crankcase cylinder sleeve using the head of piston **8** to level the piston ring.
- Measure the clearance of the piston ring gap while keeping them level and stationary. If the measured value is higher than the limit, replace the piston ring.

NOTE
- **Use piston 8 to ensure that piston rings 5 to 7 are kept level when inserting them into the crankcase cylinder sleeve.**
- **Insert piston rings 5 to 7 into the lower part of the crankcase cylinder sleeve, where the area is less worn, when measuring clearance of piston ring gap 5 to 7.**
- **Exchange the whole set of piston rings 5 to 7 as a set if any of the rings is faulty.**



(2) Clearance between piston ring and ring groove

- If the measured value is higher than the limit, replace the faulty parts.
- Measure using feeler gauge **F**, by pressing 1st compression ring **5** against piston **8** with straight edge **G**.

NOTE

- **Measurement has to be conducted around the whole periphery of piston 8 after removing carbon deposits.**
- **Be sure to exchange the whole set of piston rings 5 to 7 as a set if any of the rings is faulty.**

10 Flywheel assembly

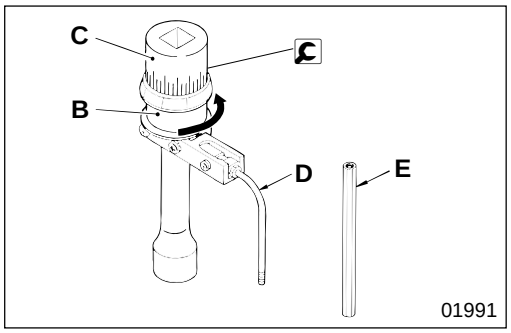
[Removal]
Bolt **2** < Manual transmission, Automatic transmission (FK617, FM617) > or **9** into extraction hole **A** of flywheel assembly **10** to remove the flywheel assembly.



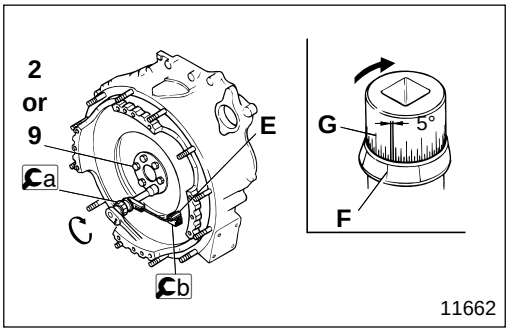
01991

[Installation]
< Manual transmission, Automatic transmission (FM657) >

- Center punch the head of bolt **2** < Manual transmission > or **9** before re-using.

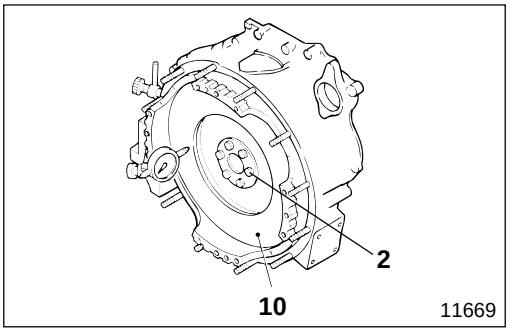
CAUTION
If there are three punches already, replace with a new bolt.

- After tightening bolt **2** < Manual transmission > or **9** at specified torque, tighten further as follows :
- Turn socket wrench holder **B** counterclockwise and maintain spring tension in the wrench.
  C : Socket
  D : Rod
  E : Rod (for connection)



11662

- Set [a] socket wrench holder **B** so that extension rod **E** maintains contact against [b] magnetic base.
- Select a scale that is convenient for reading graduation **F** on holder **B** side.
- Tighten further by turning the socket clockwise by 150° (setting is in 5° increments) referring to graduation **G** on the selected scale.

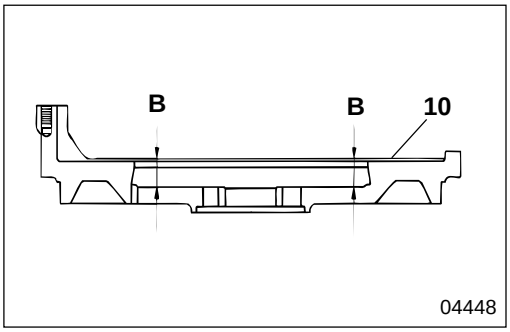


11669

[Inspection]
< Manual transmission >

(1) Runout

If the measured value is higher than the limit, check the fastening of bolt **2**, the attachment surface of crankshaft assembly, and depending on the condition found, either repair or replace flywheel assembly **10**.

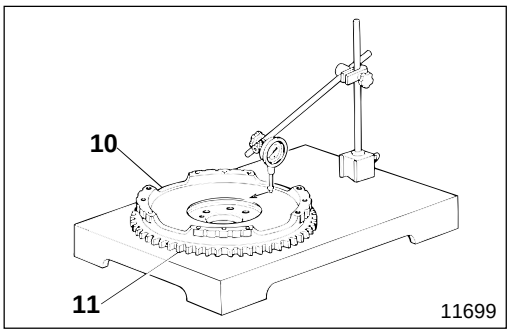


04448

(2) Thickness of friction surfaces

If the measured value is lower than the limit, repair or replace flywheel assembly **10**.

B : Thickness from bolt mounting surface to friction surface



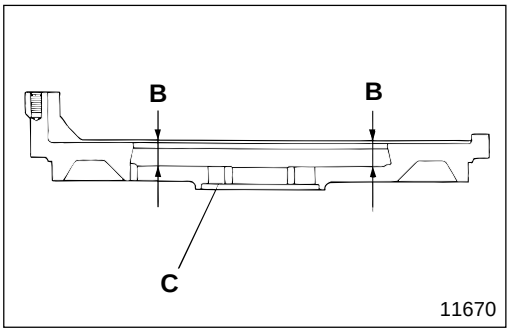
11699

(3) Distortion of friction surface

If the measured value is lower than the limit, repair or replace flywheel assembly **10**.

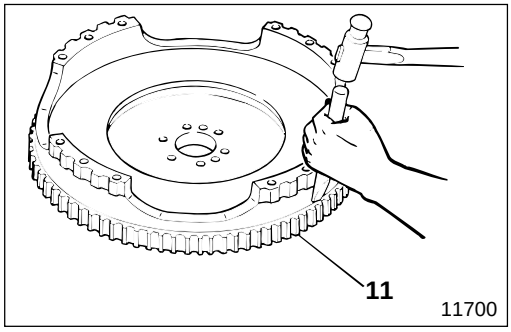
NOTE

If any fault is found in ring gear 11, replace it first, then begin the inspection.



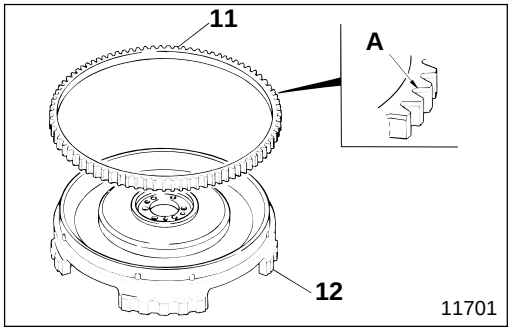
11670

[Correction]
Make sure when grinding the friction surfaces for correction, that height **B** is not lower than the limit while remaining parallel with surface **C** within 0.1 mm {0.0039 in.}.

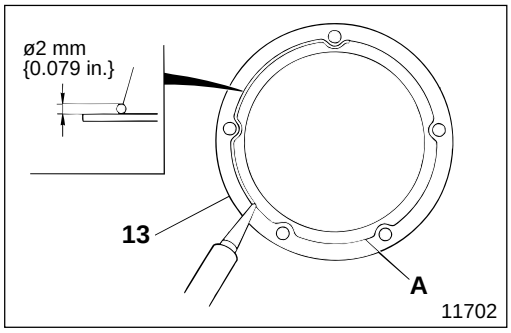


11 **Ring gear**

[Inspection]
Check and see if there is any damage, wear or other fault, and if any fault is found, replace ring gear **11**.
[Removal]
- Heat up ring gear **11** evenly using an acetylene torch.
- Hammer the outer edge of ring gear **11** evenly until it drops off.



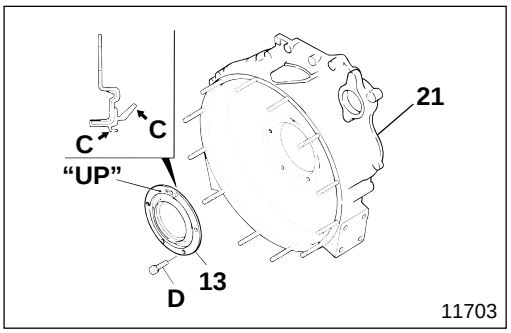
[Installation]
- Heat up ring gear **11** using a piston heater to approximately 100°C {212°F} for three minutes.
- With the side of the chamfered teeth of ring gear **11** facing you, mount it on flywheel **12**.
  A : Chamfered ring gear side



13 **Installation of rear oil seal**

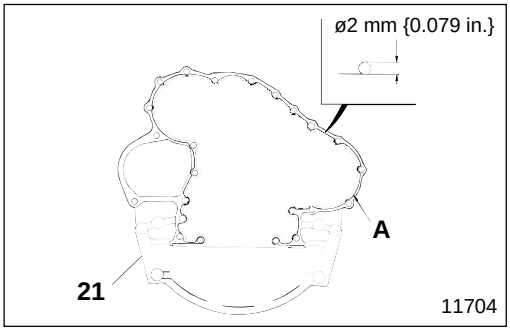
- Apply sealant **B** along line **A** of rear oil seal **13** evenly without break.

CAUTION
- **Be sure the surface of rear oil seal 13, where sealant is to be applied, is clean.**
- **Be sure not to disturb the sealant during installation.**
- **Do not start the engine for at least 30 minutes after installing rear oil seal 13.**
- **Be sure to reapply sealant B if the mounting bolts of rear seal 13 are loosened.**



- Apply engine oil to lip area **C** of rear oil seal **13**.
- Install rear oil seal **13** into flywheel housing **21** in the direction as illustrated.

CAUTION
Be sure to reapply sealant B if bolts D (for mounting rear oil seal 13) are loosened or removed by any cause whatsoever after mounting.



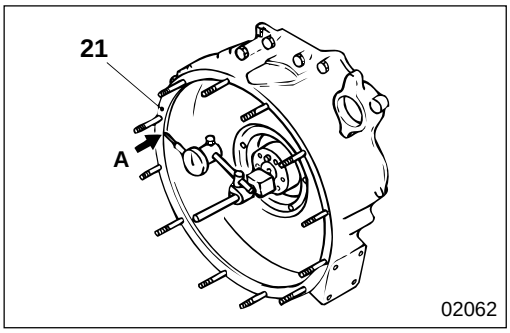
21 **Flywheel housing**

[Installation]

- Apply an even, unbroken bead of sealant **A** to the mounting surface of flywheel housing **21**, where the crankcase is to be installed.
- After applying sealant **A**, within three minutes, mount flywheel housing **21** to the crankcase.

CAUTION

- **Be sure the surface of flywheel housing 21, where the sealant is to be applied, is clean.**
- **Be sure not to disturb the sealant during installation.**
- **Do not start the engine for at least 1 hour after installing flywheel housing 21.**
- **Be sure to reapply sealant A if the mounting bolts of rear seal 21 are loosened.**



[Inspection]

- Turn crankshaft * and measure the amount of eccentricity (out-of-roundness) at mating recession **A** of flywheel housing **21**.
- Reassemble if the amount of eccentricity exceeds the limit.
- If the amount of eccentricity exceeds the limit after reassembly, replace the faulty parts.

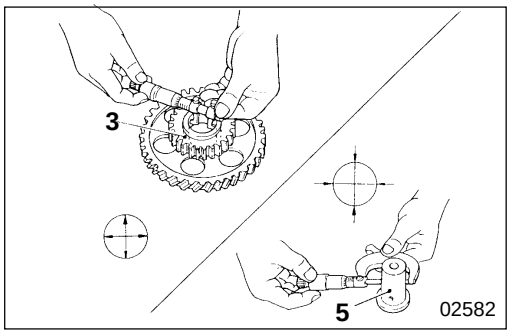
(2) No. 2 idler gear end play

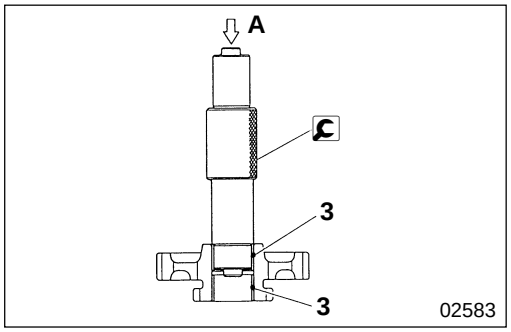
If the measurement exceeds the specified value, replace the defective part(s).



3 **5** **No. 1 idler shaft and No. 1 idler gear bushing**

[Inspection]

If the clearance exceeds the specified limit, replace the defective part(s).

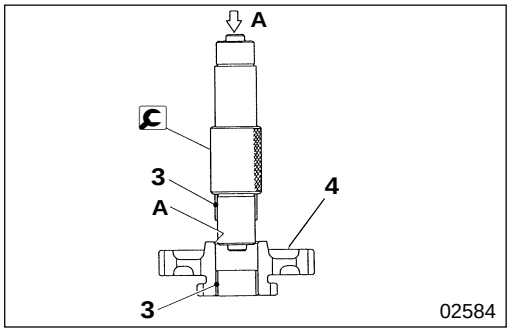


No. 1 idler gear bushing

[Removal]

The No. 1 idler gear bushing **3** consists of two pieces. Remove them at the same time.

A : Press

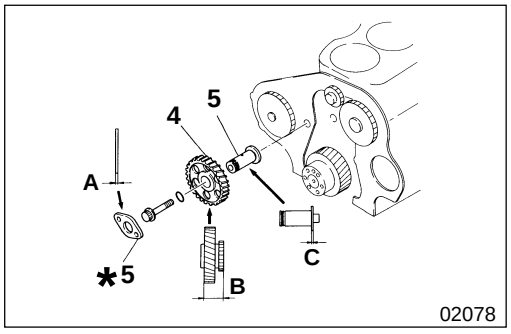


[Installation]

- Using the Idler Gear Bushing Installer, press-fit both pieces of No. 1 idler gear bushing **3** into the No. 1 idler gear **4** at the same time from the upper and lower sides.

  A: Press

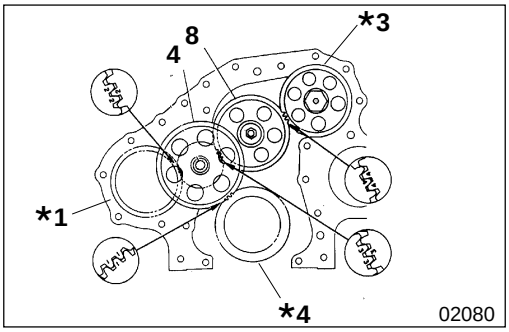
- After installation, measure the clearance again. If the measurement is below the nominal value range, ream the bushing **3**.



4 **No.1 idler gear end play**

Measure the illustrated dimensions of the parts, then calculate the end play **D**. If the end play exceeds the limit, replace the defective part(s).

72.15 mm {2.84 in.} – (A + B + C) = D



4 **8** **Installation of No. 1 and No. 2 idler gears**

- Fit the idler gears **4**, **8** such that their alignment marks "**1**", "**2**", "**3**" and "**4**" are aligned with the corresponding alignment marks.

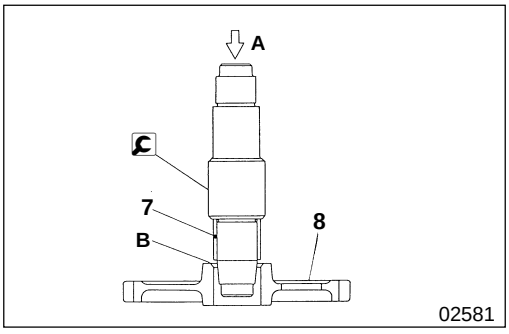
No. 2 idler gear bushing

[Removal]

A : Press



[Installation]

- Press-fit the No. 2 idler gear bushing **7** into the No. 2 idler gear **2** using the Idler Gear Bushing Installer. Install the bushing with the chamfered side **B** toward the gear.

  A : Press

- After installation, measure the clearance again. If the measurement is below the nominal value range, ream the No. 2 idler gear bushing **7**.

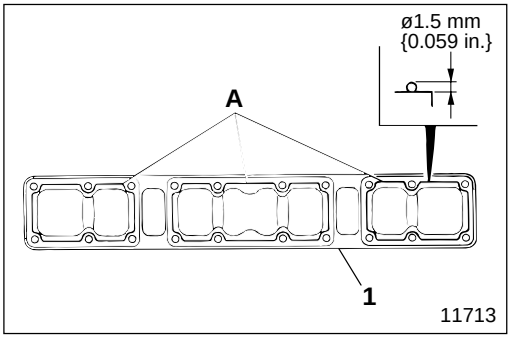
02084

● Inspection before disassembly

Camshaft end play

If the measured value is higher than the limit, replace the thrust plate.

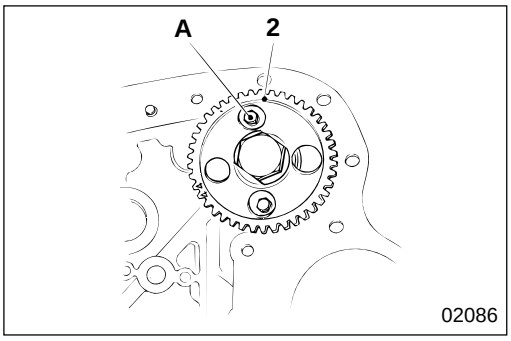


1 Installation of side cover

- Apply sealant **A** to the mounting surface of side cover **1**, evenly without break.
- After applying sealant **A**, within three minutes, mount side cover **1** to the crankcase.

CAUTION

- **Be sure the surface of side cover 1, where the sealant is to be applied, is clean.**
- **Be sure not to disturb the sealant during installation.**
- **Do not start the engine for at least 1 hour after installing side cover 1.**
- **Be sure to reapply sealant A if the mounting bolts of side cover 1 are loosened.**



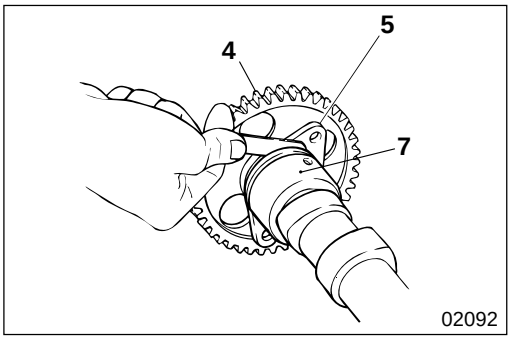
2 Camshaft assembly

[Removal]

- To remove camshaft assembly **2** first remove side cover **1**.
- Then, remove bolt **A** from the hole in camshaft gear **8**, then withdraw camshaft assembly **2** slowly, supporting it with your hand.

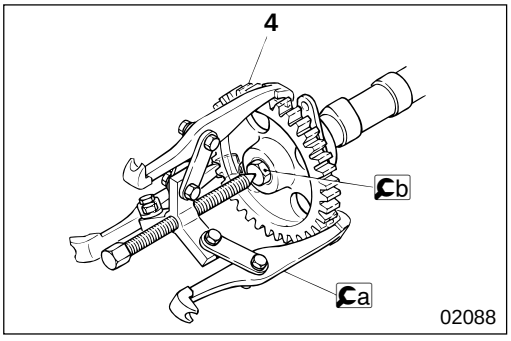
CAUTION

Be careful not to damage camshaft bushings 12 to15 when you remove camshaft assembly 2.



[Installation]

- Before installing camshaft assembly **2**, measure the end play between thrust plate **5** and camshaft **7**.
- If the measured value is higher than the limit, replace thrust plate **5**.
- Install the camshaft assembly by matching the alignment mark on camshaft gear **4** with the alignment mark on the No.2 idler gear. P11-55

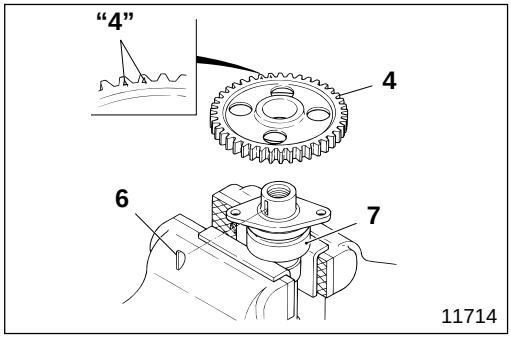


4 Camshaft gear

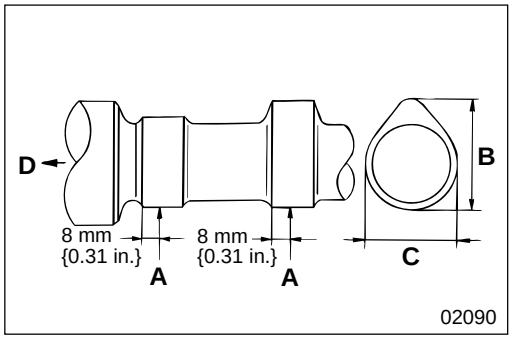
[Removal]

CAUTION

Never remove camshaft gear 4 by striking, hitting or hammering it.



[Installation]
- Install camshaft gear **4** onto camshaft **7** in the direction as illustrated.
- Be sure when finishing the installation to install key **6**.



7 Inspection of camshaft

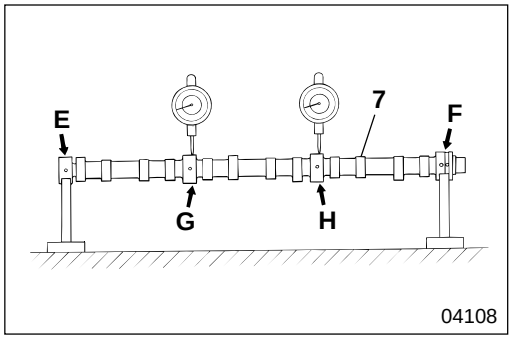
(1) Difference between short diameter and long diameter

If the measured value is lower than the limit, replace camshaft **7**.

NOTE

Measure at point A as illustrated, because the cam is tapered.

B : Long diameter
C : Short diameter
D : Front of the engine

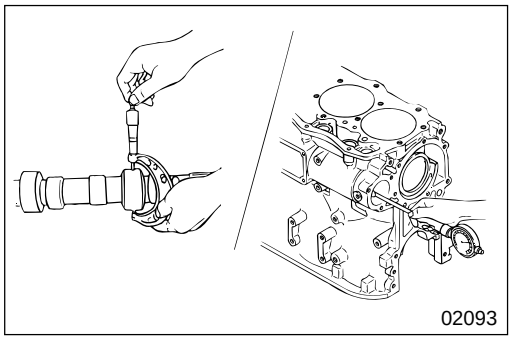


(2) Degree of bend

To measure bend, support camshaft **7** at area **E** of No.1 journal, and area **F** of No.4 journal. Then, measure the amount of bend at area **G** of No.2 journal and area **H** of No.3 journal. If any of the measured values are higher than the limit, replace the camshaft.

NOTE

The degree of bend of camshaft 7 is half of the indicated value of the gauge after rotating the shaft 360°.

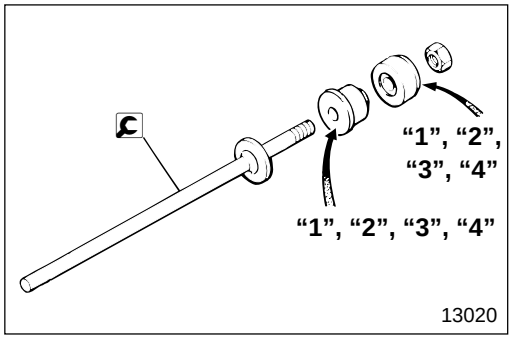


7 to 11 Camshaft and camshaft bushing

[Inspection]
If the measured value is higher than the limit, replace the faulty parts.

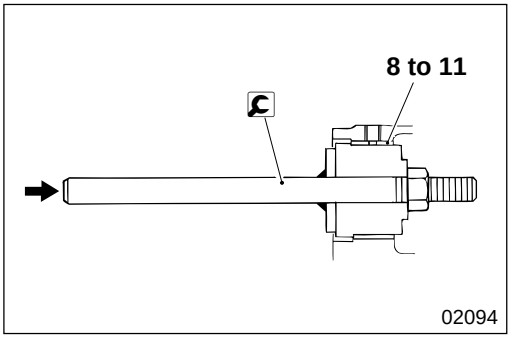
NOTE

Measure bushings 8 to 11 mounted in crankcase.



To remove or install the camshaft bushings, use 🔧 camshaft bushing installers and extractors, which have identification numbers "**1**", "**2**", "**3**" and "**4**" to identify the corresponding bushing.

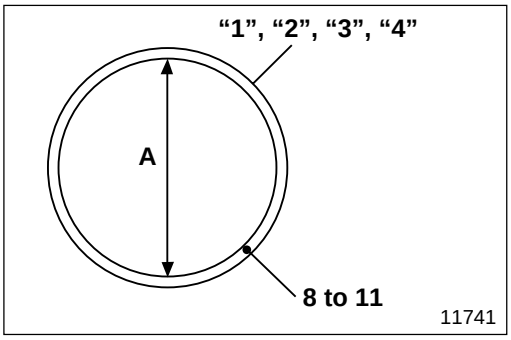
Bushing No. (From engine front)	Identification marks
1	**1**
2	**2**
3	**3**
4	**4**



Camshaft bushing

[Removal]

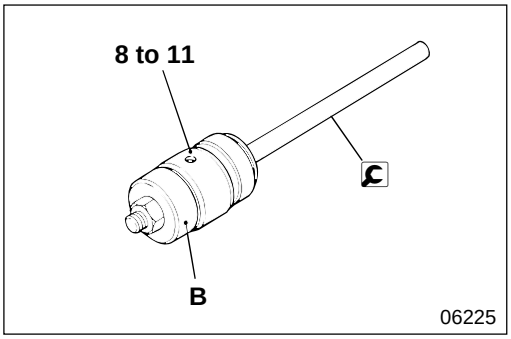
Remove No.4, 3 camshaft bushings **8**, **9** from the rear end of the engine, and No.2, 1 camshaft bushings **10**, **11** from the front end of the engine.



[Press-fitting]

- Identification numbers "**1**", "**2**", "**3**" or "**4**" on camshaft bushings **8** to **11** indicate the corresponding camshaft numbers. If the number is not clear, measure the bushing inner diameter and identify the corresponding camshaft number by referring to the table below :

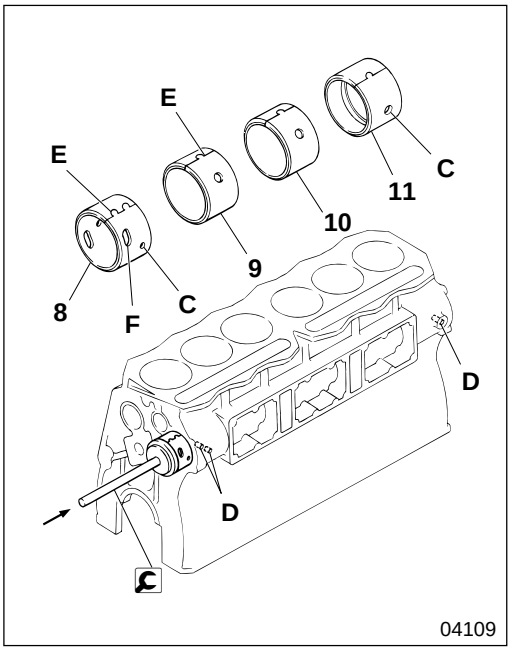
Bushing No. (From engine front)	Identification number	Inner diameter mm {in.}
No. 1	1	57.75 {2.27}
No. 2	2	58.00 {2.28}
No. 3	3	58.25 {2.29}
No. 4	4	58.50 {2.30}



- For press-fitting, mount guide **B** to camshaft bushing installer and extractor.
- Install camshaft bushings **8** to **11** in descending order from No.3 to 1.

NOTE

Install No.3, 4 camshaft bushings 9, 8 from the rear end of the engine, and No.2, 1 camshaft bushings 10, 11 from the front end of the engine.



- Install the camshaft bushings by aligning bushing oil port **C** and crankcase oil port **D** at No.1 camshaft bushing **11**, and No.4 camshaft bushing **8**.
  Position bushing No.4 so that the oblong side of oil port **F** comes to the rear of the engine and press bushing No.4 in.

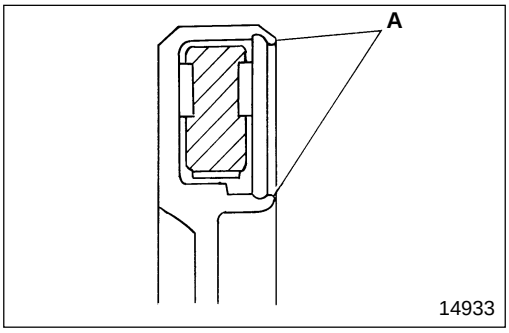
◆ Service procedure

● **Pre-disassembly inspection**

Crankshaft end play

If the measurement exceeds the specified limit, replace the defective part(s).

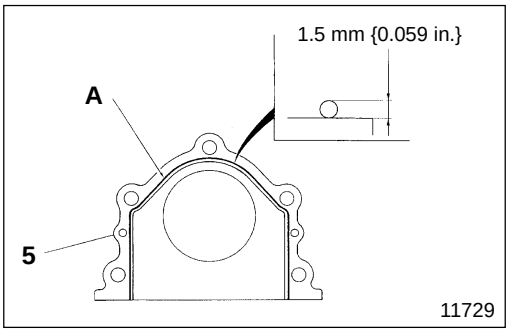


4 **Torsional damper**

CAUTION ⚠

The torsional damper is of a viscous type and filled with silicone oil. It can cause oil leaks at the staked portion A and thereby fail to function properly if handled roughly. To prevent this, pay attention to the following:

- **Ensure that the staked portion A is free from dents and other damages.**
- **Never give shocks such as by hammering or dropping it.**
- **Avoid trundling or stacking with heavy objects.**

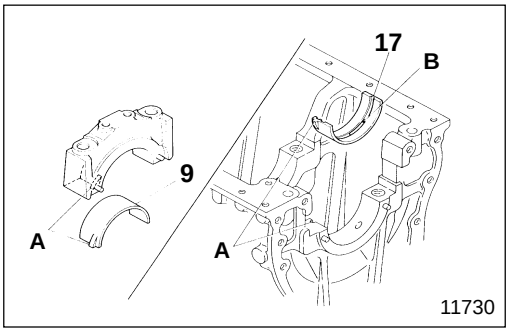


5 **Installation of front cover assembly**

- Apply an even, unbroken bead of sealant **A** to the surface of the front cover assembly **5** that contacts the crankcase **20** when installed.
- Fit the front cover assembly **5** onto the crankcase **20** within 3 minutes of applying the sealant **A**.

CAUTION ⚠

- **Ensure that the sealant application area on the front cover assembly 5 is clean before applying sealant.**
- **When fitting the front cover assembly 5, hold it firmly in position to prevent spreading the sealant.**
- **After fitting the front cover assembly 5, wait at least an hour before starting the engine.**
- **Apply a new bead of sealant A whenever the mounting bolts of the front cover assembly 5 have been loosened.**



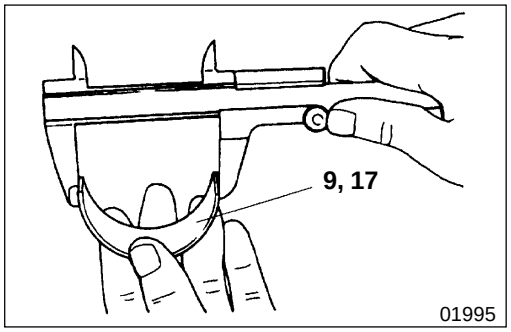
9 **17** **Main bearings**

[Installation]

Install the main bearings **9**, **17** such that their tangs **A** fit into the corresponding grooves.

CAUTION ⚠

The upper main bearing 17 has an oil hole B. The lower main bearing 9 has no oil hole. Take care not to confuse the upper and lower parts.



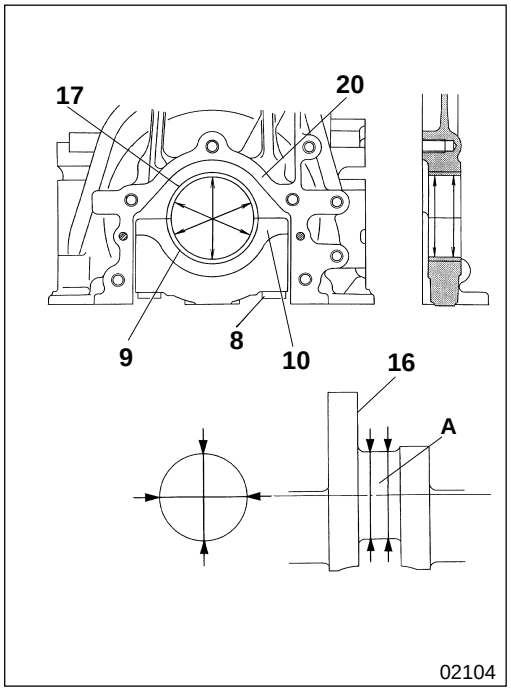
[Inspection]

CAUTION ⚠

- **Do not attempt to manually expand either bearing 9, 17 if its span is insufficient.**
- **Upper and lower bearings 9, 17 must be replaced as a set.**

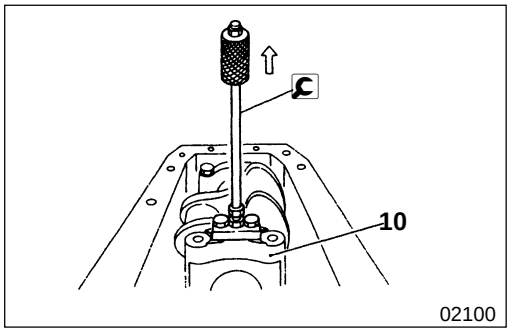
(1) Span when free

If either bearing's span when free exceeds the specified limit, the bearings **9**, **17** must be replaced.



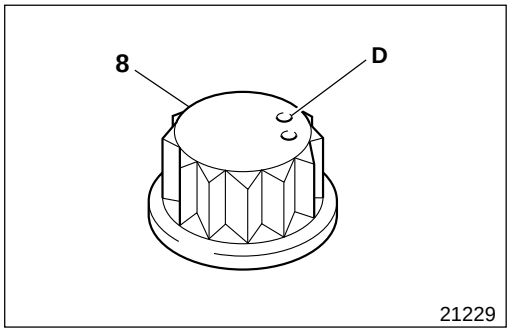
(2) Main bearing-to-crankshaft clearance

- Fit the upper main bearing **17** into the crankcase **20** and the lower main bearing **9** into the main bearing cap **10**. Then, tighten the bolts **8** to their specified torque.
- Measure the internal diameters of the main bearings **9**, **17** and the journal outside diameter **A** of the crankshaft **16**. If the clearance exceeds the specified limit, replace the defective part(s).



10 Main bearing caps

: Main Bearing Cap Extractor

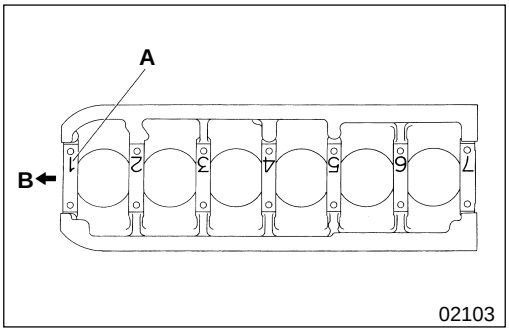


[Installation]

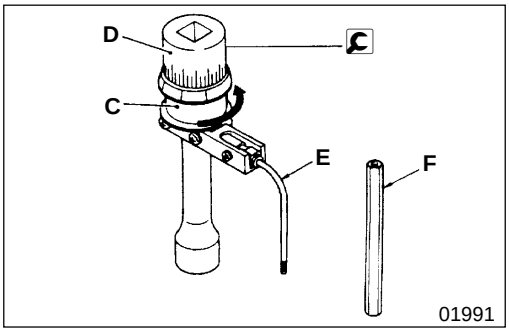
Centerpunch the head of the main bearing cap bolt.

CAUTION ⚠

- **Before fitting any bolt 8, check the punch marks D on its head. Do not use the bolt if there are more than three punch marks.**
- **The punch marks indicate the number of times each bolt has been tightened using the plastic area tightening method. Any bolt that already has three punch marks must be replaced.**

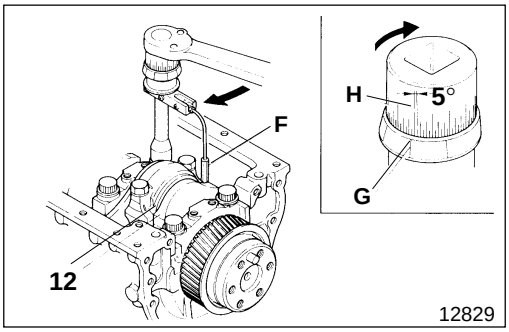


- Starting at the front of the engine **B**, fit the main bearing caps **10** in the order of the numbers **A** embossed on them and such that the numbers are in the positions illustrated.



- Tighten the bolts **8** to the specified torque. Then, turn the bolts further in accordance with the following procedure:
- Turn the holder **C** of the Socket Wrench counter-clockwise to maintain spring tension in the wrench.

  D : Socket
  E : Rod
  F : Rod (extension)

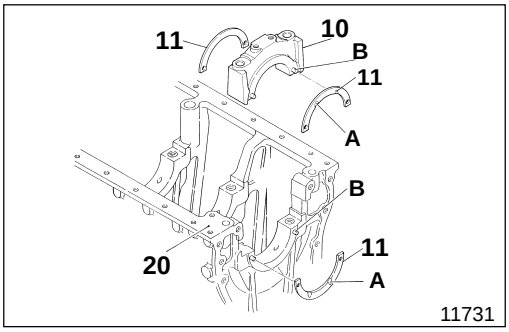


- Set the socket wrench such that the built-in spring forces the rod (extension) **F** against the crankshaft assembly **12**.
- Align any inscribed line **G** on the holder **C** with any inscribed line **H** on the socket. (Use this point as reference 0° position.)
- From the above reference position, turn the socket **D** by 90° clockwise. (One gradation on the scale represents 5°.)

CAUTION ⚠

By performing the above procedure, the bolt 8 is tightened to the plastic area. Do no attempt to tighten further after turning specified angle.

- After tightening, perform the following checks:
  - Turn the crankshaft by hand to check for smooth rotation.
  - Measure the crankshaft end play.



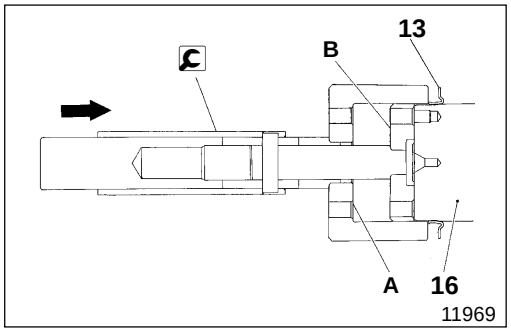
11 Installing thrust plates

Fit a thrust plate **11** on each side of the main bearing caps **10** and at the rear end of the crankcase **20** such that the oil grooves **A** are on the outside.

B : Locating pin

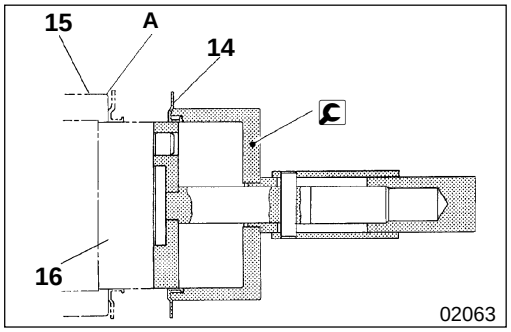
CAUTION ⚠

If any oversize thrust plates 11 are to be used, make sure that the upper and lower thrust plates installed at the rear end of the crankcase 20 are of the same size. However, the thrust plates installed on both sides of the main bearing cap 10 may be different in size.



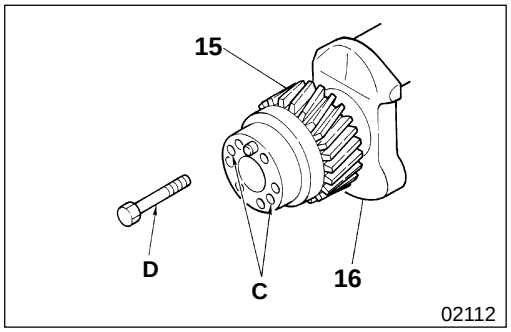
13 Installation of front oil seal slinger

Using the 🔧 Front Oil Seal Slinger Installer, drive the front oil seal slinger **13** onto the crankshaft **16** until the tool's end face **A** is pressed firmly against the guide **B**.



14 Installation of rear oil seal slinger

Using the 🔧 Rear Oil Seal Slinger Installer, drive the rear oil seal slinger **14** onto the crankshaft **16** until it touches the end surface **A** of the crankshaft gear **15**.



15 Crankshaft Gear

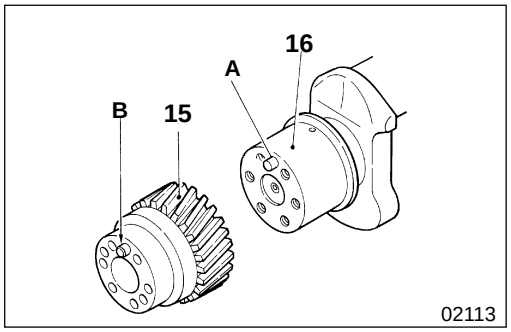
< With flywheel power take-off >

[Removal]

Screw the flywheel mounting bolts **D** evenly into the threaded holes **C** in the crankshaft **16** to remove the gear. The gear can also be removed by using the 🔧 Gear Puller.

CAUTION ⚠

Do not tap off the crankshaft gear 15 since this could damage it.



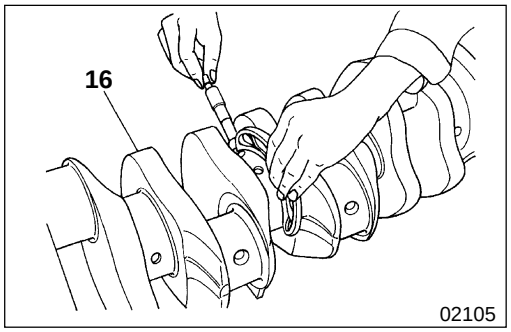
[Installation]

- Using a piston heater or the like, heat the crankshaft gear **15** to a temperature of approximately 100°C {212°F}.

WARNING ⚠

Be careful not to get burned.

- Align the locating pin **A** on the crankshaft **16** with the dowel pin **B** on the crankshaft gear **15**. Then, drive the gear into position by striking its end face with a plastic mallet.

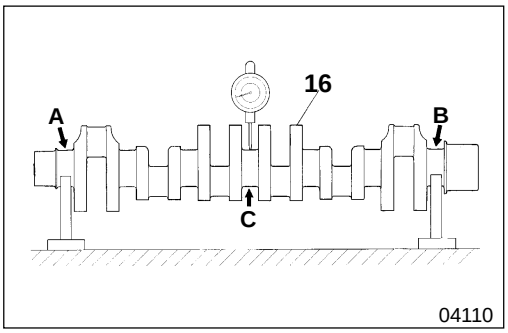


16 Crankshaft

[Inspection]

(1) Roundness and taper of crankshaft journal and pin

If either measurement exceeds the specified limit, grind it to undersize or replace the crankshaft **16**.

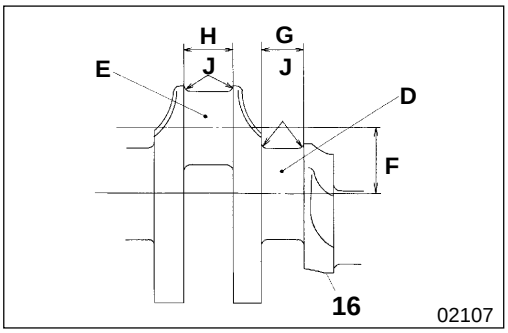


(2) Bend

- Support the crankshaft **16** at its No.1 journal **A** and No. 7 journal **B**. Measure the extent of bending in the crankshaft at the center of the No.4 journal **C**.
- If the measurement exceeds the specified limit, replace the crankshaft.

CAUTION ⚠

Turn the crankshaft 16 through one revolution. One-half of the dial indicator reading represents the extent of bending.



[Rectification]

CAUTION ⚠

If the crankshaft 16 is rectified by grinding, the main bearings 9, 17 must be replaced with undersized ones.

- Grind such that the center-to-center distance **F** between the journal **D** and pin **E** never be changed.

  F: $57.5\ ^{+0.025}_{-0.075}$ mm $\left\{2.26\ ^{+0.00098}_{-0.00295}\ \text{in.}\right\}$
- Grind such that the journal width **G** and pin width **H** do not change.

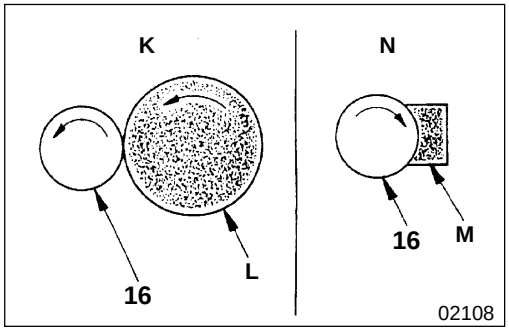
  G: 37 mm {1.45 in.}

  H: $42\ ^{+0.2}_{0}$ mm $\left\{1.65\ ^{+0.0078}_{0}\ \text{in.}\right\}$
- Finish the corner fillet smoothly and to the specified radius **J**.

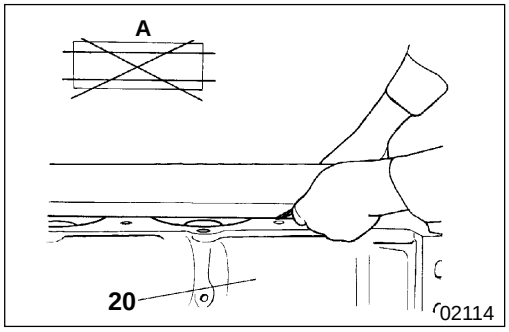
  J: R5 ± 2 mm {R0.02 ± 0.0079 in.}
- Carry out a magnetic inspection to check for cracks caused by grinding. Also, check that the Shore hardness of the surface has not dropped below Hs 75.

Crankshaft undersize dimensions — Unit: mm {in.}

	Degree of undersize			
	0.25 {0.0098}	0.50 {0.020}	0.75 {0.030}	1.00 {0.039}
Finished journal diameter	83.685 to 83.705 {3.294 to 3.295}	83.435 to 83.455 {3.284 to 3.285}	83.185 to 83.205 {3.274 to 3.275}	82.935 to 82.955 {3.265 to 3.266}
Finished pin diameter	64.67 to 64.69 {2.5460 to 2.5468}	64.42 to 64.44 {2.5362 to 2.5370}	64.17 to 64.19 {2.5263 to 2.5271}	63.92 to 63.94 {2.5165 to 2.5173}
Roundness	0.01 {0.00039} or less			
Cylindricity	0.006 {0.00024} or less			



- When grinding **K**, turn the crankshaft **16** counter-clockwise as viewed from its front end. The grinder **L** should rotate in the same direction.
- When finishing **N** the crankshaft **16** with whetstone or sandpaper **M**, rotate the crankshaft clockwise.



20 **Inspecting crankcase upper surface distortion**

If distortion exceeds the specified limit, correct it with a surface grinder.

A : Measurement positions

CAUTION ⚠

When grinding the crankcase 20, take care that the piston projections stay within specification.

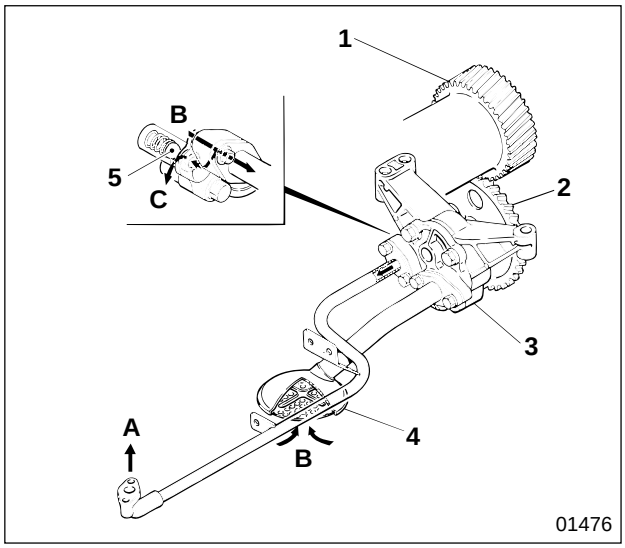
Oil Pump

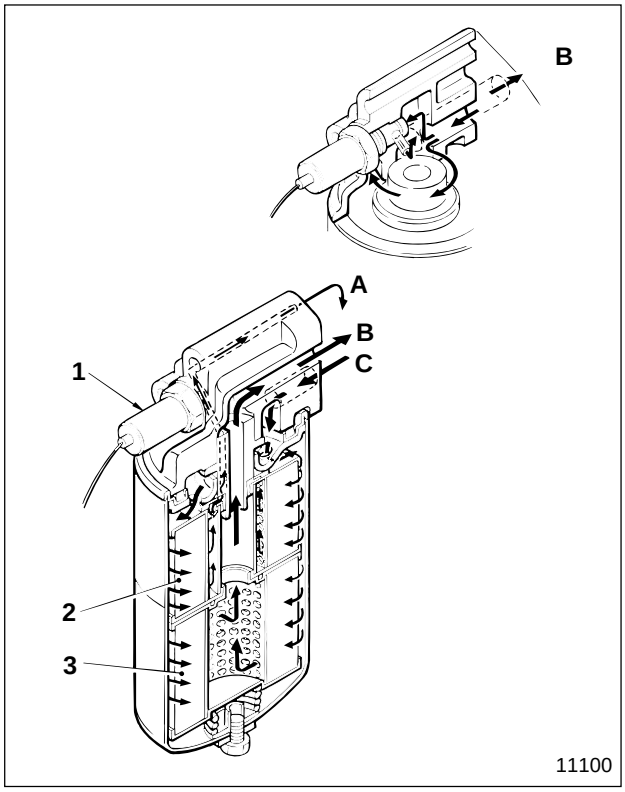


1 Crankshaft gear
2 Oil pump gear
3 Oil pump
4 Oil strainer
5 Relief valve

A : To oil filter
B : From oil pan
C : To oil pan

Oil pump **3** is a gear type, driven by rotation of the crankshaft transmitted by crankshaft gear **1** that engages oil pump gear **2**. Relief valve **5** is installed on the oil pump and when the oil pump discharge pressure becomes higher than standard, part of the engine oil is returned to the oil pan by relief action of the valve, protecting the lubricating system from breakdown caused by excessive oil pressure.

Oil Filter



1 Engine oil bypass alarm switch
2 Bypass filter element
3 Full-flow filter element

A : To oil pan
B : To oil cooler
C : From oil pump

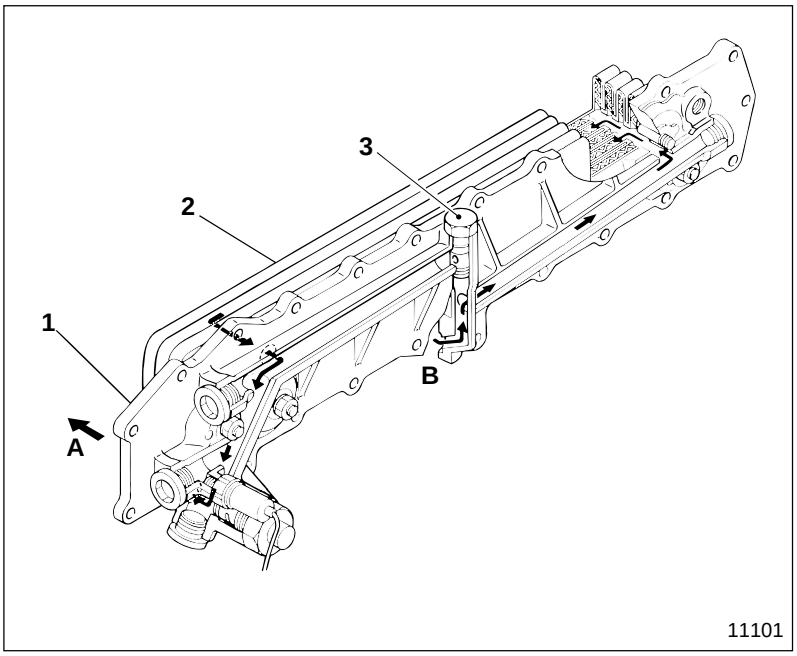
This oil filter uses a spin-on filter paper type element that integrates full-flow filter element **3** and bypass filter element **2**.

Operation of engine oil bypass alarm switch

- When the oil filter element is clogged, the engine oil pressure on flow becomes low and might cause seizure of engine parts, engine oil bypass alarm switch **1** is installed to prevent this.

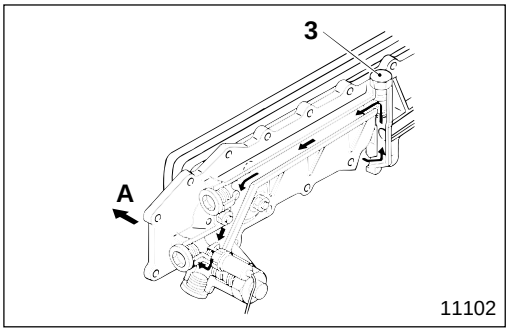
- When the oil filter element is clogged, engine oil bypass alarm switch **1** lets the engine oil flow directly to oil cooler **B**, bypassing full-flow filter element **3**. When the engine oil bypass alarm switch is activated it lights the warning lamp, warning the driver that the oil filter element is clogged.

Oil Cooler



1 Oil cooler cover
2 Oil cooler element
3 Bypass valve

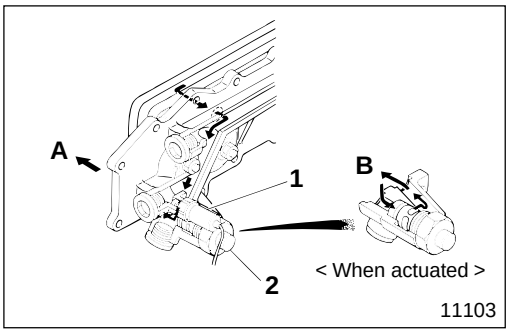
A : To main oil gallery
B : From oil filter



● **Bypass valve**

When the viscosity of the engine oil is high at low temperatures, or when oil cooler element **2** is clogged, flow resistance is high, and if this happens, bypass valve **3** opens to let the engine oil return directly to main oil gallery **A** without going through the oil cooler.

Engine Oil Pressure Switch, Regulator Valve



1 Engine oil pressure switch
2 Regulator valve

A : To main oil gallery
B : To oil pan

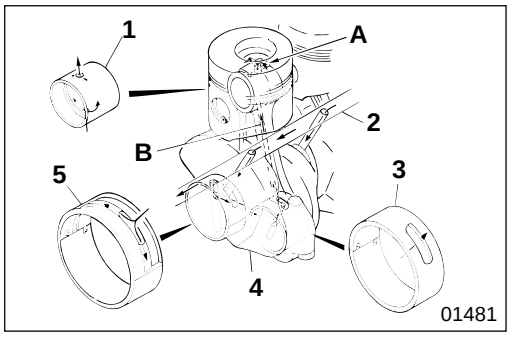
● **Engine oil pressure switch**

When pressure for delivering the engine oil to main oil gallery **A** becomes lower than standard, the built-in electric contact point of engine oil pressure switch **1** closes to light warning lamp in the meter cluster, warning the driver that the oil pressure is abnormal.

● **Regulator valve**

When the oil pressure in the main oil gallery becomes higher than standard, regulator valve **2** opens to let part of the engine oil return to oil pan **B**, thereby regulating the oil pressure.

Lubrication of Related Parts



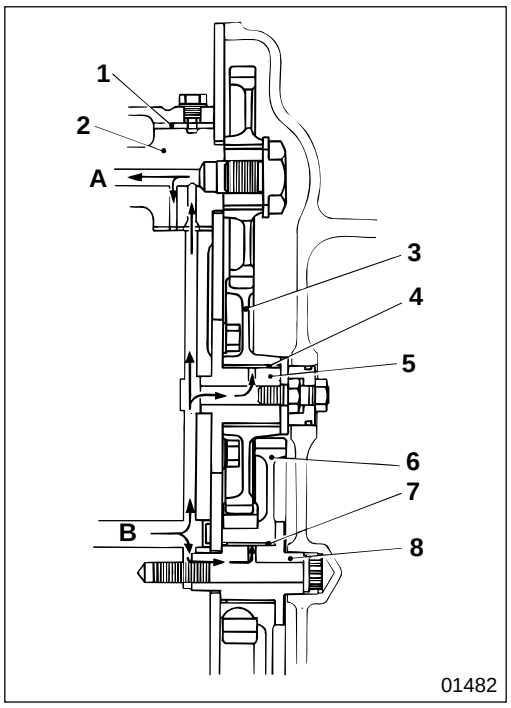
Engine oil delivered to the main oil gallery lubricates the following related parts.

● **Main bearing and connecting rod bearing**

1 Connecting rod bushing
2 Main oil gallery
3 Main bearing
4 Crankshaft
5 Connecting rod bearing

A : Oil jet
B : Connecting rod oil passage

Engine oil supplied through the oil passage drilled in crankshaft **4** flows through connecting rod oil passage **B** to lubricate the small end of the connecting rod, the engine oil then sprays out oil jet **A** at the top of the connecting rod to cool the piston.

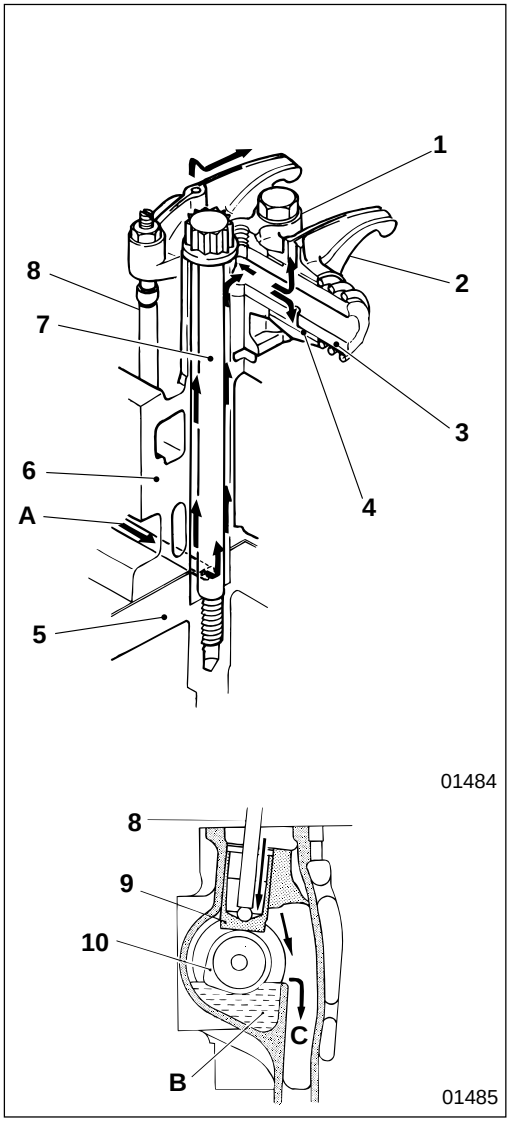


● **Timing gear and camshaft**

1 Camshaft bushing No.4
2 Camshaft
3 Idler gear No.2
4 Idler gear bushing
5 Idler gear shaft No.2
6 Idler gear No.1
7 Idler gear bushing
8 Idler gear shaft No.1

A : To rocker bushing
B : From main oil gallery

Engine oil flows through the inside of camshaft **2** and lubricates each camshaft bushing.

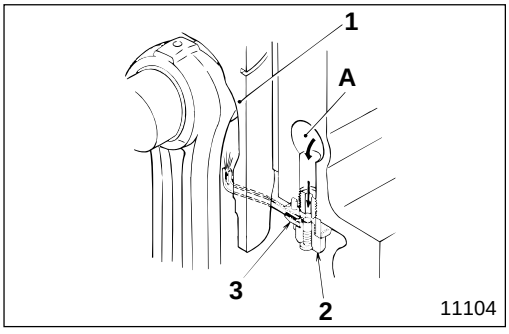


● **Valve mechanism**

1 Rocker shaft bracket
2 Rocker
3 Rocker shaft
4 Rocker bushing
5 Crankcase
6 Cylinder head
7 Cylinder head bolt
8 Push rod
9 Tappet
10 Camshaft

A : From No.4 camshaft bushing
B : Oil sump
C : To oil pan

Engine oil is lead to oil reservoir **B** to lubricate camshaft tops after lubricating rocker **2**, camshaft bushing, etc.

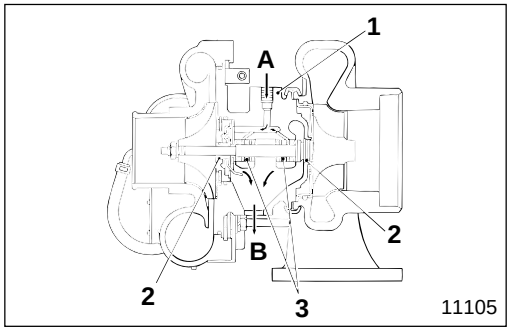


● **Oil jet**

1 Piston
2 Check valve
3 Oil jet

A : Main oil gallery

An oil jet **3** is installed, in the lower part of main oil gallery **A**, for each cylinder and cools pistons **1** by injecting engine oil toward the inside of the piston. The oil jet is fitted with check valve **2** which opens and closes at standard oil pressure levels. This prevents a decrease of oil volume at low oil pressure as well as a decrease of oil pressure itself.

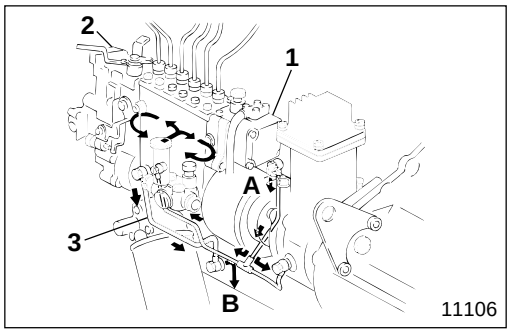


● **Turbocharger**

1 Bearing housing
2 Piston ring
3 Bearing

A : From main oil gallery
B : To oil pan

Engine oil is delivered from the main oil gallery to bearing housing **1** through the oil pipe to lubricate the inside of the bearing housing. Piston ring **2** installed at both ends of the turbine wheel shaft works as an oil seal.

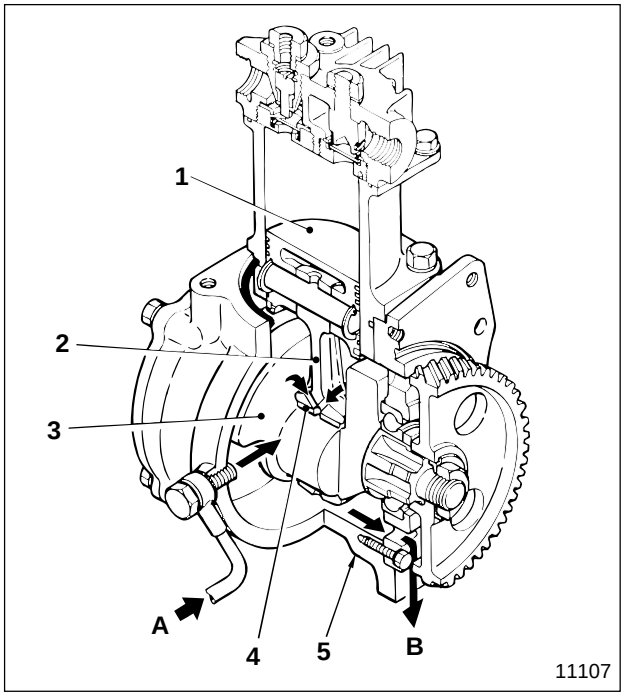


● **Injection pump**

1 Injection pump
2 Governor
3 Oil return pipe

A : From main oil gallery
B : To oil pan

Engine oil that has lubricated injection pump **1** and governor **2** returns to the oil pan through oil return pipe **3**.

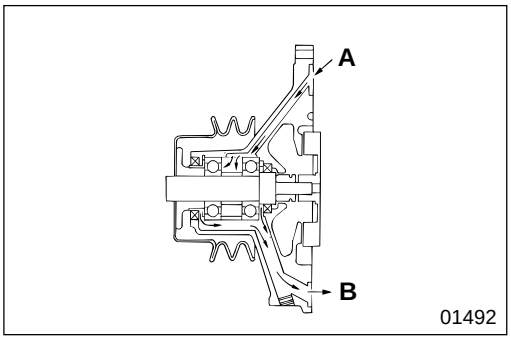


● **Air compressor**

1 Piston
2 Connecting rod
3 Crankshaft
4 Connecting rod bushing
5 Crankcase

A : From main oil gallery
B : To oil pan

Engine oil from the main oil gallery splashes connecting rod **2** and lubricates connecting rod bushing **4**. Then the rotation of crankshaft **3** splashes engine oil onto piston **1** and the small end of the connecting rod to lubricate them.



● **Water pump**

A : From oil main gallery
B : To oil pan

[Installation]

- Clean the surface of oil filter head **3** that makes contact with oil filter **2**.
- Apply engine oil thinly and evenly to gasket area **A** of oil filter **2**.
- Screw in oil filter **2** to oil filter head **3** until gasket area **A** contacts the oil filter head.
- From this position, tighten further by rotating by one and one eighth to one and three eighths of a turn.
- Install oil filter drain plug **1**.
- After installation, run the engine and check that there is no oil leakage from gasket area **A**.
- Check the engine oil level and if it is low, fill to correct level.

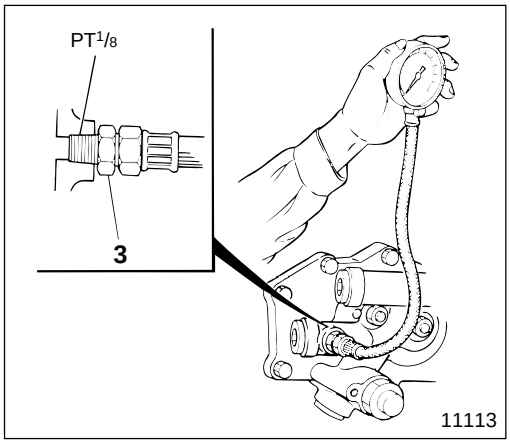
- Remove oil pressure switch **2** from oil cooler **1**.
- Mount the oil pressure gauge after installing adaptor **3** onto oil cooler **1**.
- Warm up the engine until the oil temperature reaches 70 to 90°C {158 to 194°F}.
- Measure oil pressure at no-load minimum revolution and at no-load maximum revolution. If the measured values are lower than the limit, overhaul the lubricating system.



- After measurement, install engine oil pressure switch **2** and tighten at specified torque.

CAUTION

Be sure to install oil pressure switch 2 when the engine is cold.

◆ Service procedure

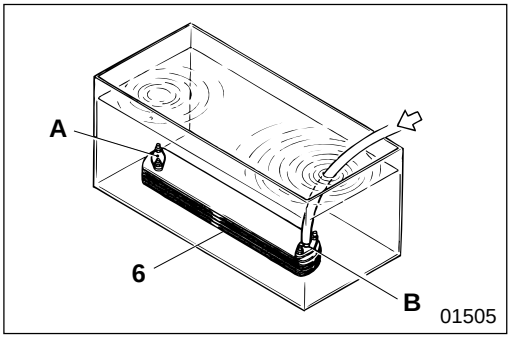
● Cleaning

- Check and see if any carbon deposits or sludge have developed in the oil passage of oil cooler element **7** or its bypass. Clean any deposits off thoroughly with cleaning solvent.
- Also clean any water scale found in oil cooler element **7** or oil cooler cover **10**. Gr 14.



7 Inspection of oil cooler element

- Immerse oil cooler element **7** in a water tank after plugging exit port **A** and connecting the hose to engine oil entry port **B**.
- Apply air pressure of 1470 kPa {215 psi, 15 kgf/cm^2} via the hose and see if there is any air leakage from any part of oil cooler element **7**.
- If you see any leakage, replace oil cooler element **7**.

Fuel in fuel tank **3** is sucked up by feed pump **7** which is driven by the cam action of injection pump **8** and is filtered through fuel filter **2** which removes dirt and other foreign particles.
Filtered fuel is sent to the injection pump where the fuel pressure is boosted and injected through injection nozzle **1** into the combustion chamber.
When fuel pressure is higher than the specified value, overflow valve **9** opens to let the fuel return to the fuel tank **3**.

● **Accelerator pedal switch**

Accelerator pedal switch **1** detects whether the accelerator pedal assembly **8** is depressed.

● **Accelerator pedal position sensor**

Accelerator pedal position sensor **2** detects the movement of the accelerator pedal assembly **8** and sends the information to the engine electronic control unit in the form of electrical signals. The accelerator position sensor lever **3** is pulled in the idling position direction **A** by the return spring.

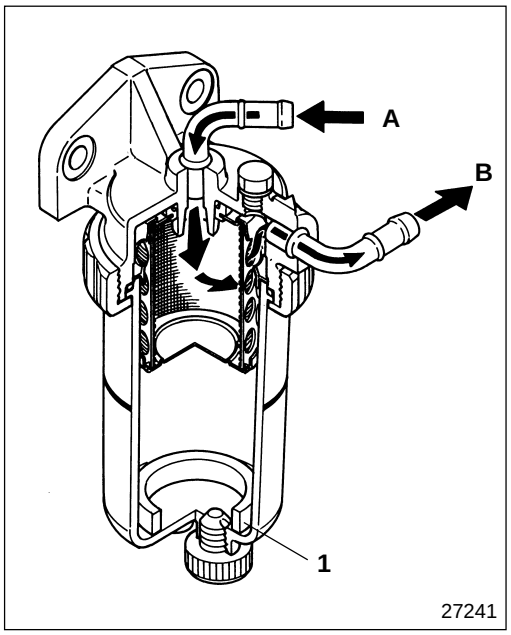
● **Emergency engine stop button**

The engine is generally stopped electrically by setting the starter switch **4** to the off position.
However, if the engine does not stop by setting the starter switch to the off position because of malfunctions in the electronic governor system, etc., pulling the emergency engine stop button **5** moves the electronic governor stop lever **6** to the stop position **C** and stops the engine.

CAUTION⚠

If the engine was stopped by pulling the engine stop button 5, the control unit computer must be reset by setting the starter switch 4 to the ACC or LOCK position.
If the engine is restarted without resetting the computer, the engine revolution control will be unstable.

Water Separator

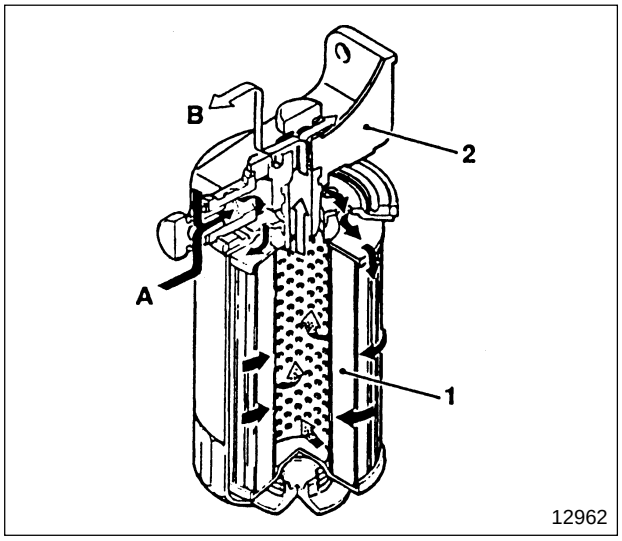


1 Water level ring

A : From fuel tank
B : To feed pump

The water separator is installed between the fuel tank and the feed pump. Any water present in the fuel is separated by the baffle plate and the screen assembly.

Fuel Filter



1 Fuel filter
2 Fuel filter head

A : From feed pump
B : To injection pump

Pressurized fuel is delivered from the feed pump of the injection pump to the fuel filter which separates water from the fuel and removes foreign particles from the fuel by fuel filter **1**.

- The electronic governor and pre-stroke control injection pump system combines an electronic governor **6** with an injection pump **7** that has an electronically controlled pre-stroke adjustment feature.
- The injection pump's plunger lift speed varies in accordance with the engine speed, causing concomitant variations in the injection pipe pressure.
- Variations in the injection pipe pressure make it difficult to achieve an optimum spray from the injection nozzles and the optimum air/fuel mixture.
- To compensate for changes in the injection pipe pressure, the injection pump plunger pre-stroke is increased at low and mid- range speeds, thus ensuring that fuel injection takes place late in the cam lift, when plunger movement is relatively fast.
- At high speeds, the plunger pre-stroke is decreased, thus ensuring that fuel injection takes place in early in the cam lift, when plunger movement is relatively slow. Excessive increases in injection pipe pressure are thus prevented.
- By adjusting the plunger pre-stroke in this manner, the pre-stroke control injection pump **7** ensures that the spray and air/ fuel mixture are always optimally suited to combustion.
- The overall benefits are higher engine torque and cleaner exhaust emissions than are possible with a conventional injection pump.
- Control operations are performed by the engine electronic control unit **41**, which receives data from sensors on the engine and other vehicle components, processes them, and issues appropriate drive signals to the pre-stroke actuator **8** (located at the rear of the injection pump) and to the linear DC motor **3** (located inside the electronic governor).

The system's control functions (including auxiliary functions) are shown in the following table.

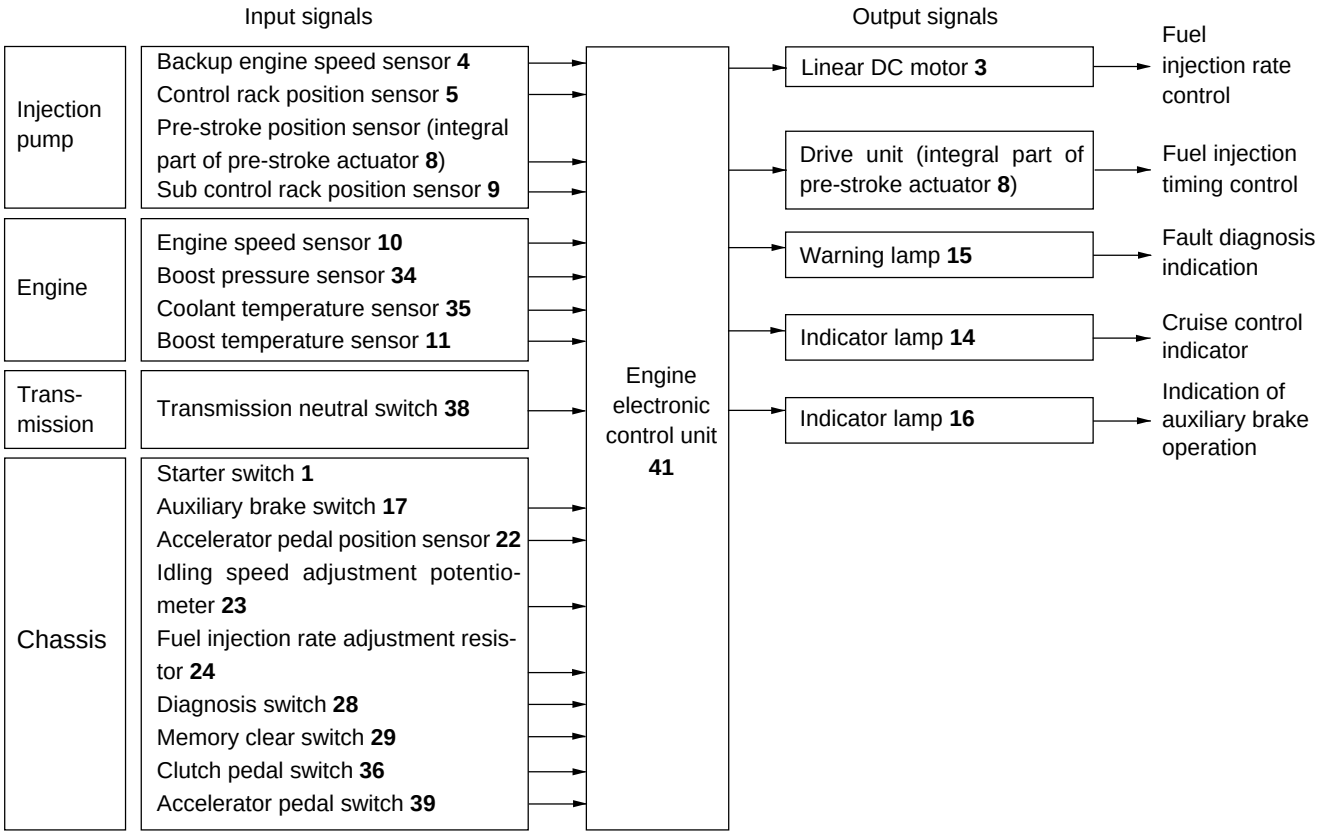
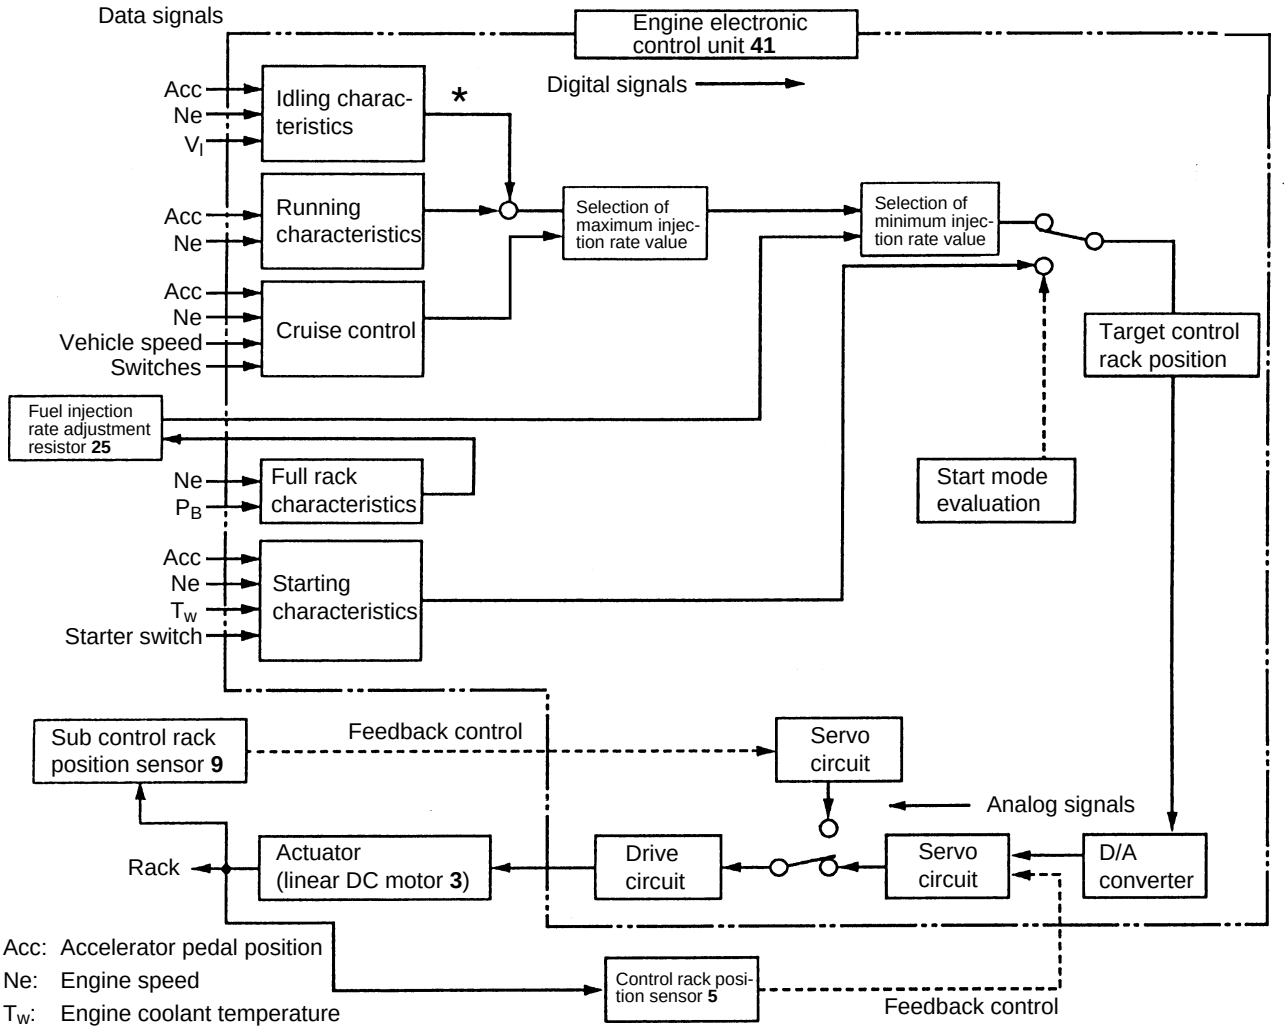
System Block Diagram



● Fuel injection rate control



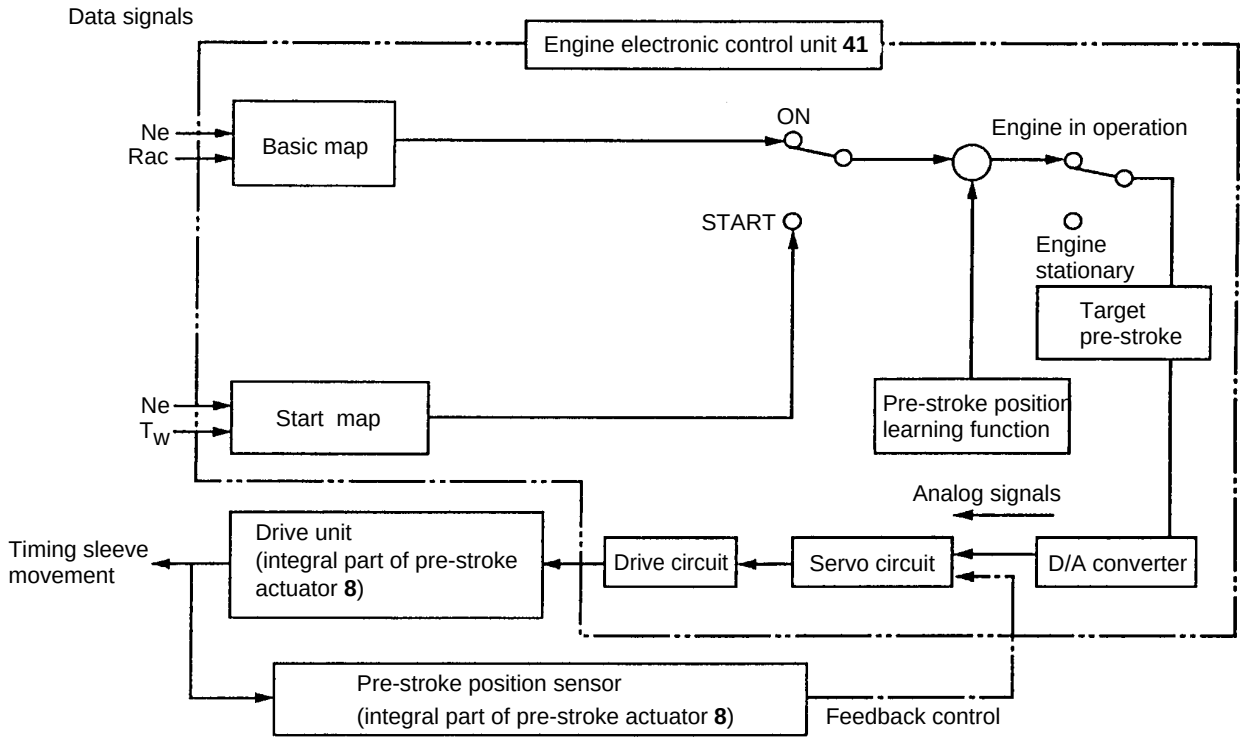
Operation of engine electronic control unit 41

- During engine operation control is effected in accordance with the cruise control, idling characteristics and running characteristics. The maximum fuel injection rate value is selected in accordance with the output signals.
- After this selection, the control unit calculates and determines the minimum injection rate to prevent the injection rate selected in accordance with the full rack characteristics from exceeding the maximum injection rate. The target control rack position is thus determined. (During engine startup, control is effected in accordance with the starting characteristics, with the target rack position determined directly in accordance with the data signals.)
- The determined control rack position signal is converted into a continuous analog signal. By way of the servo circuit and drive circuit, the signal is applied to the linear DC motor **3**, which moves the rack.

Operation of control rack position sensor 5

- The control rack position sensor **5** monitors the operation of the linear DC motor **3**. In accordance with the position of the control rack, the sensor determines whether the linear DC motor is operating in accordance with the target, and it transmits feedback signals to the engine electronic control unit **41**.
- In accordance with the feedback signals, the engine electronic control unit **41** calculates the actual control rack position. If the actual position differs from the target, the control unit issues a correction command.
- Through repetition of this process, the system ensures that the control rack position complies with the target at all times.

● Pre-stroke control



Rac: Control rack position
Ne: Engine speed
T_W: Engine coolant temperature
D/A converter: Digital-to-analog converter

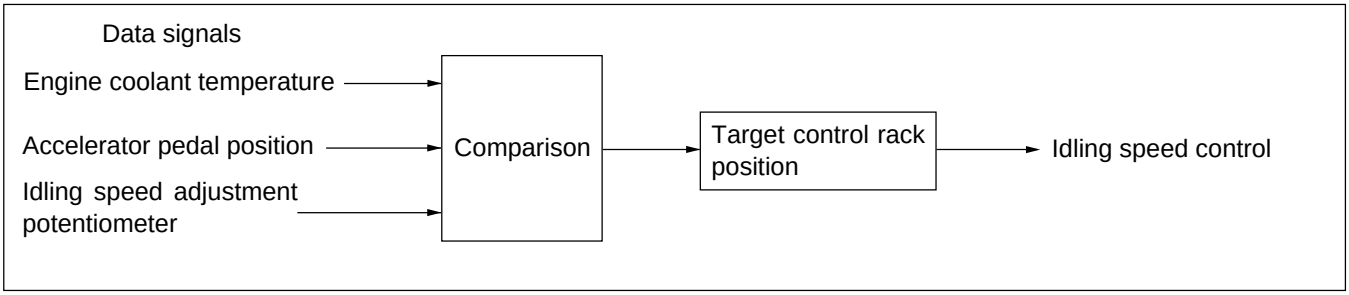
Operation of engine electronic control unit 41

- During engine operation, control is effected in accordance with the basic map.
- The pre-stroke position learning function compensates for pre-stroke position sensor adjustment errors and other injection pump errors using the pre-stroke position sensor output voltage, thereby enabling determination of the target pre-stroke.
- The determined target pre-stroke value is converted into a continuous analog signal. By way of the servo circuit and drive circuit, the signal is applied to the drive unit. The drive unit moves the timing sleeve to alter the pre-stroke.
- During engine startup, control is effected in accordance with the start map.

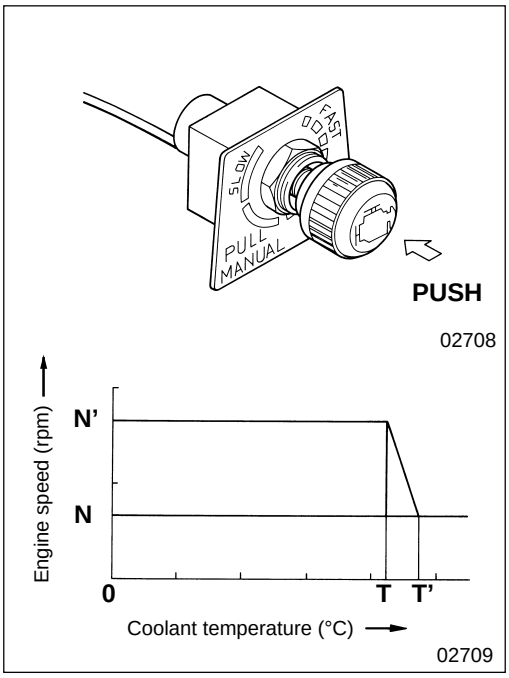
Operation of pre-stroke position sensor (integral part of pre-stroke actuator 8)

- The pre-stroke position sensor monitors the operation of the drive unit. In accordance with the position of the timing sleeve, the sensor determines whether pre-stroke control is being performed in accordance with the target, and it transmits feedback signals to the engine electronic control unit **41**.
- In accordance with the feedback signals, the engine electronic control unit **41** calculates the actual timing sleeve position. If the actual position differs from the target, the control unit issues a correction command.
- Through repetition of this process, the system ensures that the timing sleeve position complies with the target at all times. The appropriate pre-stroke is achieved as a result.

● Warmup time shortening function

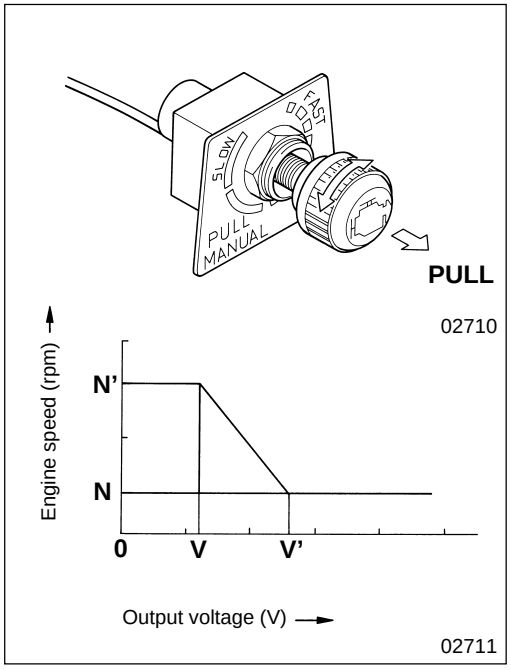


The warmup time shortening function increases the engine's idling speed in accordance with the coolant temperature, thereby shortening the time required for the engine to warm up. Control is effected automatically or manually in accordance with the position of the idling speed adjustment potentiometer **23**. Automatic control is selected by pushing the potentiometer, and manual control is selected by pulling it.



Automatic control (Potentiometer pushed)

- Automatic control is selected when the idling speed adjustment potentiometer **23** is pushed.
- When the coolant temperature is low, the engine's idling speed is automatically increased to shorten the time required for warmup.
- If the coolant temperature increases from **T** to **T'** (see the graph), the engine speed is decreased from **N'** to **N**. thus returning to its standard idling level.



Manual control (Potentiometer pulled)

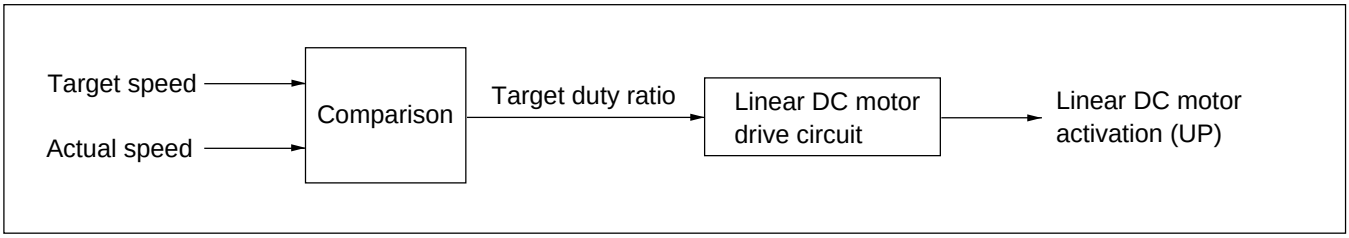
- When the idling speed adjustment potentiometer **23** is pulled, the automatic mechanism is cancelled. The driver can then adjust the idling speed as desired by rotating the potentiometer. (Rotation of the potentiometer causes the potentiometer's output voltage to change accordingly.)
- With the output voltage between **0** and **V**, the engine speed stays at the **N** to **N'** level.
- If the output voltage is increased from **V** to **V'** (see the graph), the engine speed decreases from **N'** until it reaches its standard idling level **N**.

● Emergency vehicle operation function (Used of event in control rack position sensor fault)

Fault in Control rack position sensor 5

In the event of a fault in the control rack position sensor **5**, detection of the control rack position is performed using the sub control rack position sensor **9**. This enables more-or-less normal vehicle operation.

Fault in control rack position sensor 5 and sub control rack position sensor 9



In the event of faults in both the control rack position sensor **5** and sub control rack position sensor **9**, the position of the rack, which is controlled by the linear DC motor **3**, cannot be sensed directly. The fuel injection rate cannot be controlled normally with the engine in this condition. As an emergency measure, therefore, control operations are performed in accordance with engine speed data signals only. For this function, target engine speeds for given degrees of accelerator pedal depression are pre-programmed into the engine electronic control unit **41**. Control is effected as follows:

- The target engine speed is compared with the actual engine speed (this is indicated by the engine speed sensor **10**).
- The target duty ratio is determined in accordance with the result of the comparison. In accordance with the target duty ratio, a drive signal is transmitted to the UP-side (speed increasing side) circuit to effect control over the engine speed. If the target engine speed exceeds the actual engine speed or vice versa, the UP-side circuit's ON time period is altered such that the target engine speed is maintained.

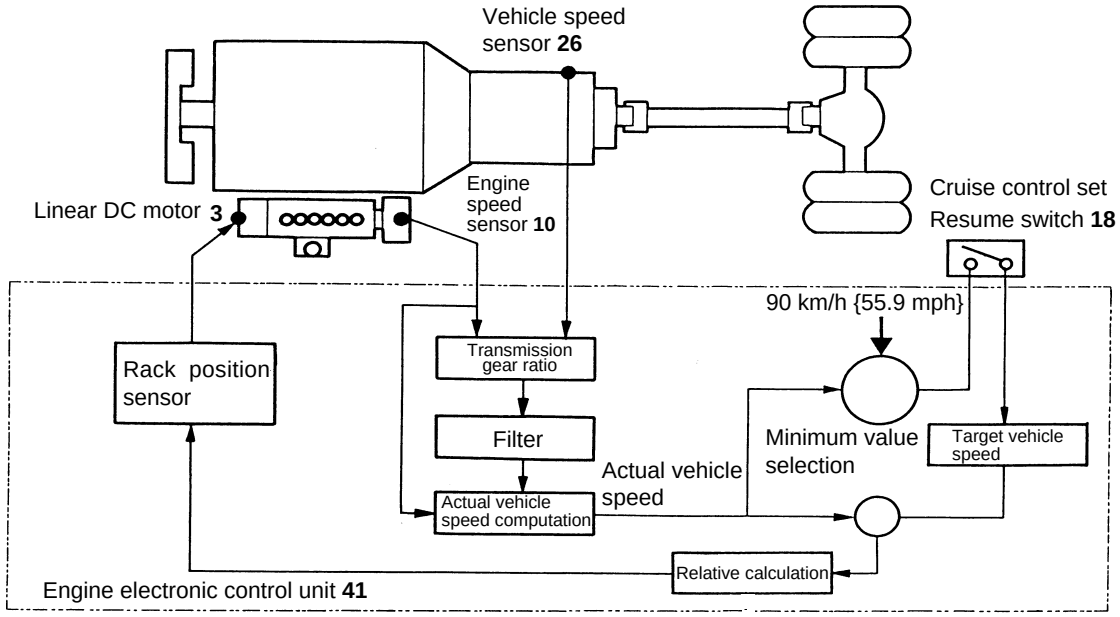
The target duty ratio is the ratio of the time periods during which the linear DC motor's UP-side and DOWN-side (speed decreasing side) circuits are energized. It is calculated as follows:

$$\text{Duty ratio} = \frac{\text{UP-side circuit ON time period}}{\text{UP-side circuit ON time period + DOWN-side circuit ON time period}} \times 100\%$$

CAUTION ⚠

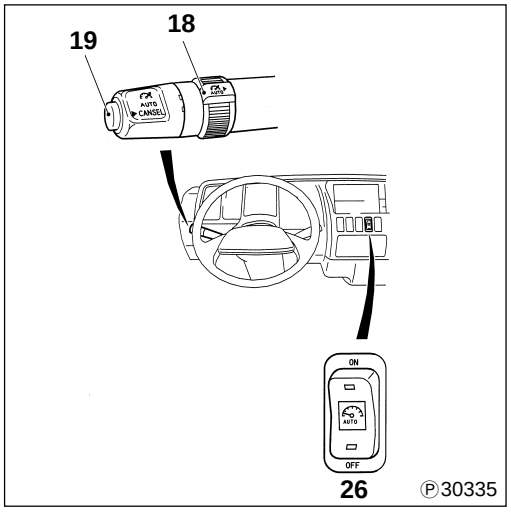
When this function is activated, the warning lamp 15 flashes to indicate that the engine must be inspected immediately. 🕮 **P13-32**

● Cruise control function



25930

- The transmission gear ratio is calculated based on the information from the vehicle sensor **26** and the engine speed sensor **10**.
- The actual vehicle speed is calculated from the gear ratio and the engine revolution speed.
- The cruise control vehicle speed is set to the minimum of the maximum possible vehicle speed and the calculated actual vehicle speed.
- By setting the desired vehicle target speed, the difference between the set speed and the actual vehicle speed is calculated and the target rack position is determined.
- This command is sent to the linear DC motor **3** as an operational signal and thus an even vehicle speed can be maintained by controlling the rack position.



Ⓟ30335

The cruise control should be operated using the cruise control set switch **19** and the resume switch **18** as follows.

CAUTION ⚠

The following conditions must be satisfied for cruise control to operate.

- **The vehicle speed must be between 40 to 90 km/h {25 to 55.9 MPH} and the gear shift lever must be in the 4th position or higher.**
- **The cruise control main switch 28 must be ON.**
- **The exhaust brake must be OFF.**
- **The clutch and the brake pedal must be in released.**

Cruise control set resume switch 18

SET side

This switch is used to set and change the cruise vehicle speed.

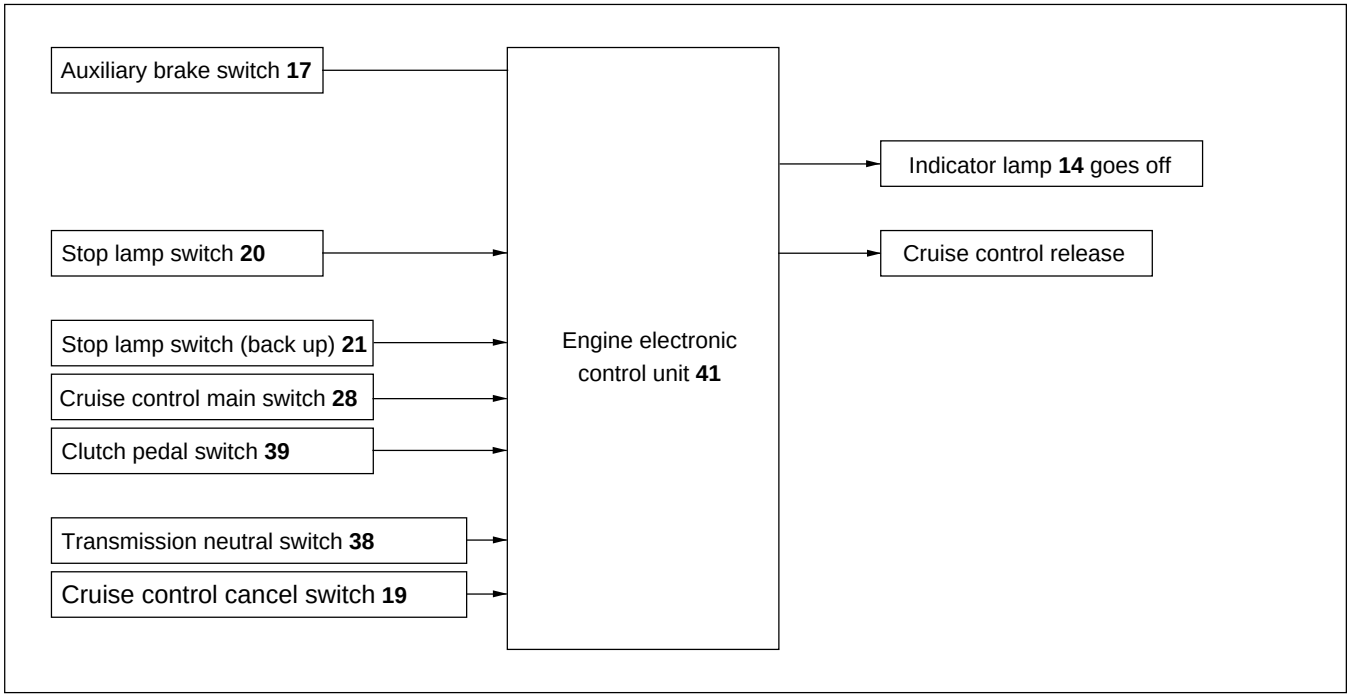
- Setting the cruise speed
  Set the vehicle speed at your discretion by operating the accelerator pedal.
  Turn cruise control set/resume switch **18** to SET, and the cruise speed will be set to the current vehicle speed when it is released. The indicator lamp will light up at the same time.
- Reducing the cruise speed
  With cruise control in activation, vehicle speed decreases while cruise control set/resume switch **18** is turned to SET. Release the switch when the vehicle reaches a desired speed to set cruise control at that speed.
- Increasing the cruise speed
  Press the accelerator pedal. When the vehicle reaches a desired speed, turn cruise control set/resume switch **18** to SET and release it immediately. The vehicle continues traveling at the set speed.

RESUME side

To restore or change vehicle speed setting.

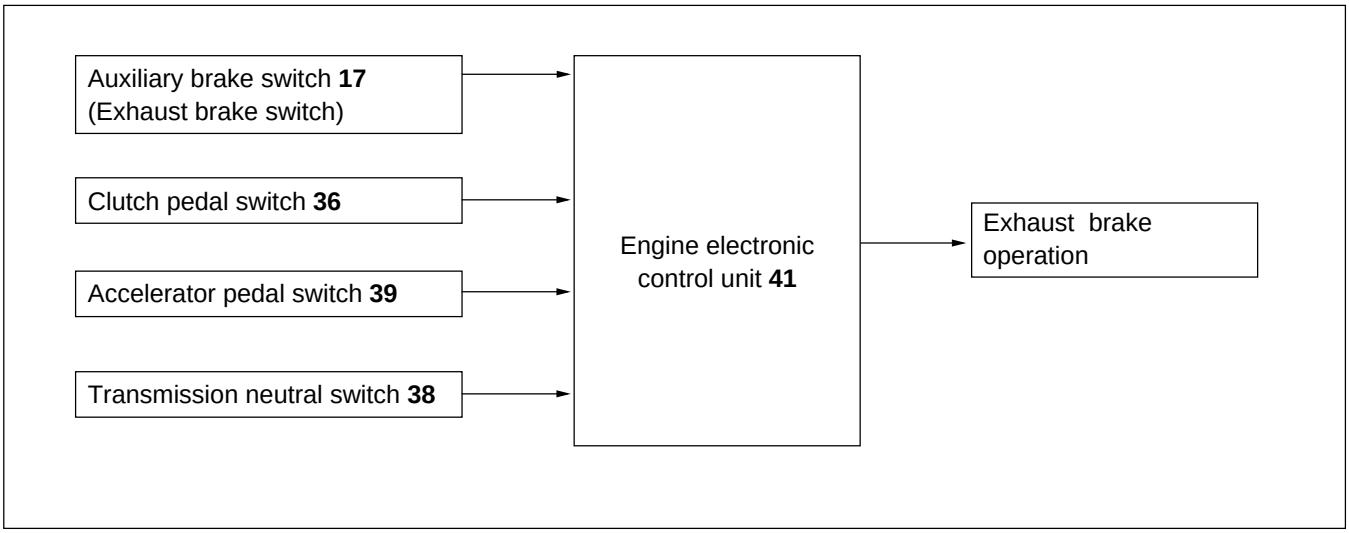
- Restoring previous vehicle speed setting when cruise control is deactivated by deceleration, turning and releasing cruise control set/resume switch **18** will restore the previous vehicle speed setting.
- Increasing the set vehicle speed setting with cruise control in activation, turning cruise control set/resume switch **18** to RESUME will increase vehicle speed. When the switch is released, vehicle speed at that time is set as cruise control speed.

Cruise control release



The cruise control is disengaged or temporarily disabled when the switches are in the following conditions.
< Disengaged >
Cruise control main switch **28** OFF
< Temporarily disabled >
- Auxiliary brake switch **17** ON
- Clutch pedal switch **39** ON (Depressing the clutch pedal)
- Transmission neutral switch **38** OFF (Transmission in neutral position)
- Stop lamp switch **21** ON (Depressing the brake pedal)
- Cruise control cancel switch **19** ON

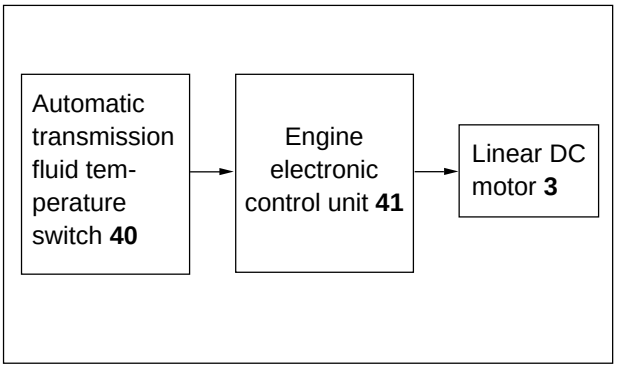
● Auxiliary brake control function



The auxiliary brake control function acts upon the auxiliary braking devices, i.e., the exhaust brake, when the following conditions are satisfied:

- Clutch pedal switch **36**: OFF (clutch pedal released)
- Accelerator pedal switch **39**: ON (accelerator pedal released)
- Transmission neutral switch **38**: ON (transmission not in neutral)

● Injection control function in high ATF temperature condition < Automatic transmission >



When the temperature of automatic transmission fluid exceeds the normal range, automatic transmission fluid temperature switch **40** turns ON. When engine electronic control unit **41** detects this rack limit switch operation, it controls linear DC motor **3** to reduce the engine output power.

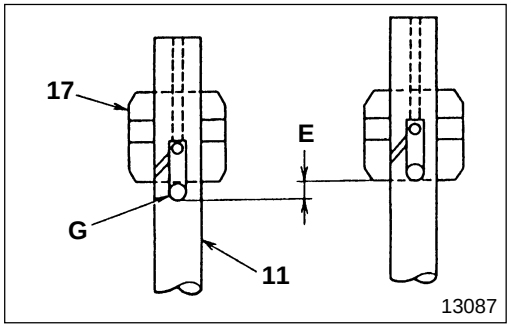
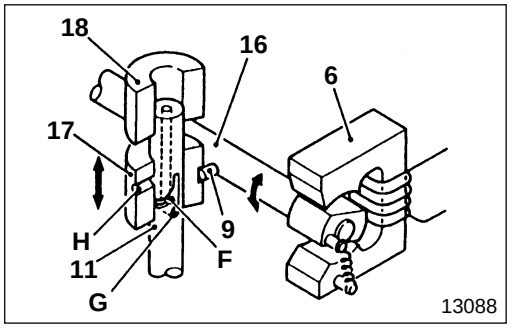
D : Electronic governor

- The injection pump is provided with a mechanism that enables variation of the plunger pre-stroke.
- Variation of the plunger pre-stroke enables the creation of air/fuel mixture and spray conditions that are optimally suited to combustion. The overall benefits are higher engine torque and cleaner exhaust emissions than are possible with a conventional injection pump.



Pre-stroke

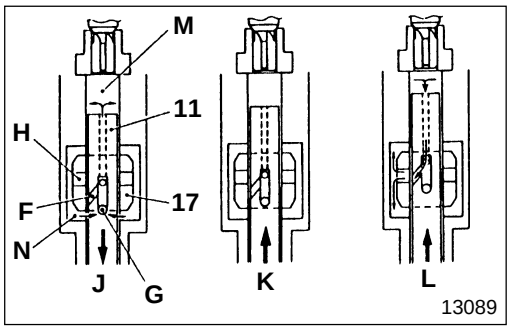
The term “pre-stroke” refers to the stroke dimension **E** of a plunger **11** from the plunger’s bottom dead center position to the point at which its fuel inlet hole **G** is closed by the timing sleeve **17** and fuel injection begins. This stroke dimension is constant in a conventional injection pump.



Variable pre-stroke mechanism

F : Lead
G : Inlet hole
H : Outlet hole

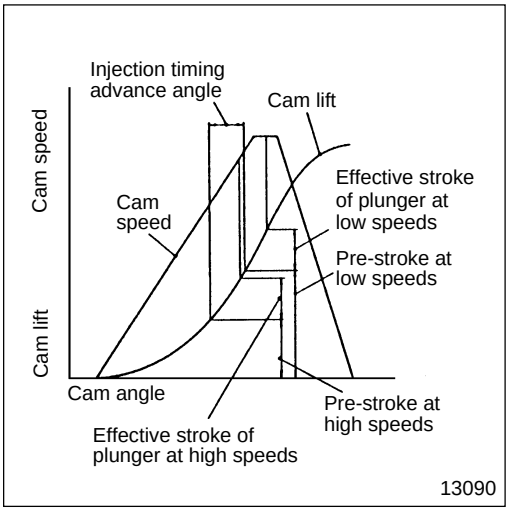
- In contrast to the fixed plunger barrel arrangement of a conventional injection pump, each plunger barrel **18** in the pre-stroke control type injection pump incorporates a vertically moveable timing sleeve **17**.
- Movement of the timing sleeve is effected by the timing rod **16**, pin **9**, and drive unit **6**.
- When the drive unit **6** rotates the timing rod **16**, the pin **9** moves the timing sleeve **17** up or down accordingly.
- Since the timing sleeve **17** incorporates a fuel outlet hole **H**, the pre-stroke changes in accordance with the movement of the timing sleeve.



Fuel feed action

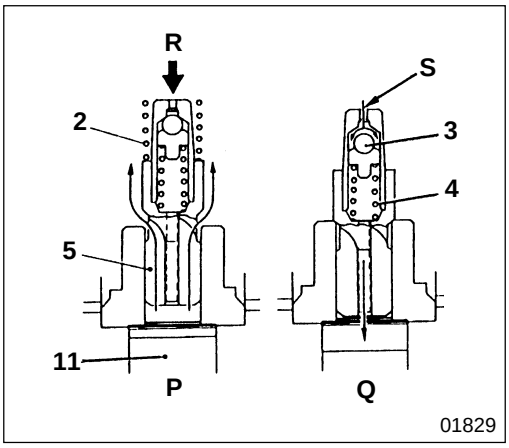
J : Fuel intake
K : Start of pressurization
L : End of pressure feed

- As the plunger **11**, moves downward from its top dead center position and its inlet hole **G** opens, fuel flows into the pressure chamber **M** owing to the vacuum pressure created by the plunger’s downward movement and the fuel pressure produced by the feed pump.
- When the plunger **11** moves upward but its lift dimension is still small, the fuel in the pressure chamber **M** escapes into the sump **N** through the inlet hole **G** in the plunger. Thus, the pressure in the pressure chamber does not increase.
- As the plunger **11** moves further upward and the inlet hole **G** is closed by the timing sleeve **17**, the fuel starts to be pressurized. The pressure increases as the plunger moves upward, and the injection pump starts to feed the pressurized fuel to each injector.
- When the lead **F** in the plunger **11** becomes aligned with the outlet hole **H** in the timing sleeve **17**, the fuel in the pressure chamber **M** returns to the sump **N**, thus completing the pressure feed cycle.
- Adjustment of the injected fuel volume is achieved by rotation of the plunger **11**, which alters the position of the outlet hole **H** in the timing sleeve **17** relative to the lead **F** in the plunger.



Fuel injection timing and fuel injection characteristics

- Changes in the position of the timing sleeve **17** cause concomitant changes in the pre-stroke, which in turn alter the fuel injection timing.
- A decrease in the pre-stroke causes the fuel inlet hole **G** in the plunger **11** to close earlier such that the fuel injection timing is advanced.
- This arrangement provides highly responsive control over the injection timing and thus enhances the engine's cold startability.

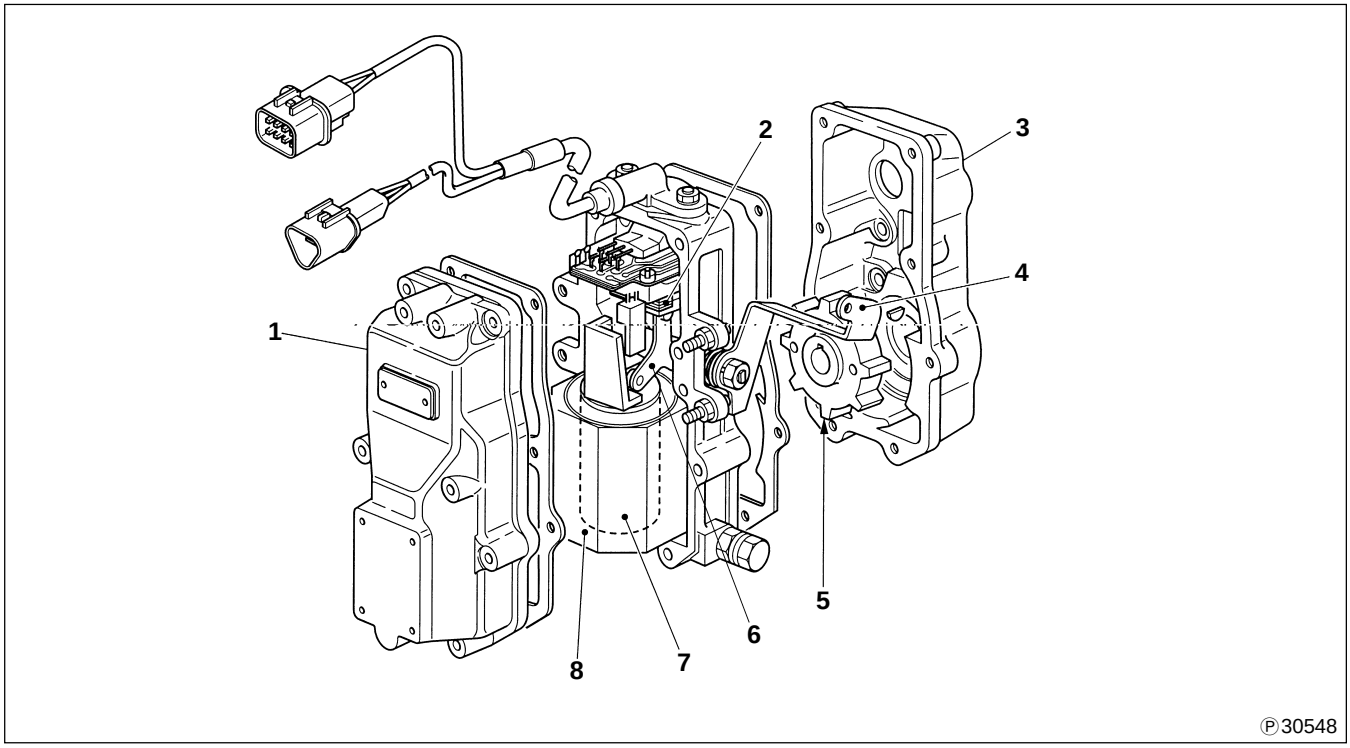


Delivery valve

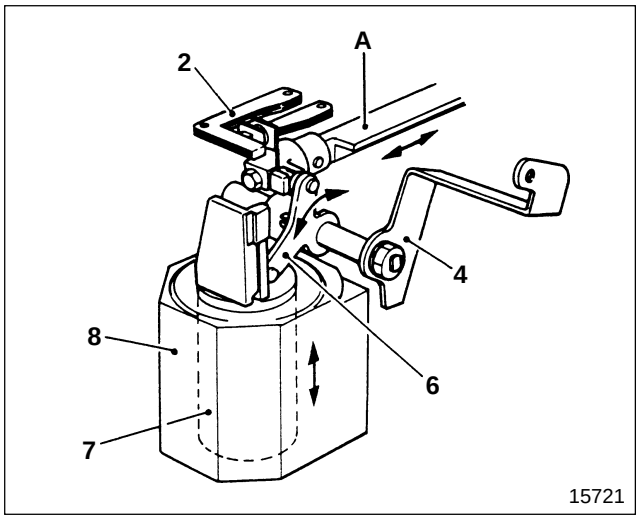
P : Start of pressure feed
Q : End of pressure feed

- The delivery valve **5** keeps constant the residual pressure **R** in the injection pipe at all engine speeds. This operation prevents the generation of bubbles in the fuel (this is known as "cavitation") and thus enables fuel injection at a high pressure.
- When the plunger **11** moves upward and the pressure of the fuel pushed by the plunger overcomes the residual pressure **R** in the injection pipe and the preset force of the delivery valve spring **2**, the delivery valve is pushed upward and delivery of the pressurized fuel begins.
- As soon as fuel delivery is complete, the fuel in the injection pipe rapidly returns to the plunger side and the delivery valve closes.
- Surplus fuel slowly returns through the orifice **S**, thus reducing the pressure in the injection pipe.
- When the preset force of the spring **4** in the delivery valve **5** is exactly offset by the pressure in the injection pipe, the ball **3** closes the orifice **S**, thus ensuring that the residual pressure **R** in the injection pipe remains constant.

Electronic Governor



1 Cover
2 Control rack position sensor
3 Housing
4 Emergency engine stop lever
5 Sensing gear
6 Link
7 Linear DC motor
8 Coil assembly



● Linear DC motor

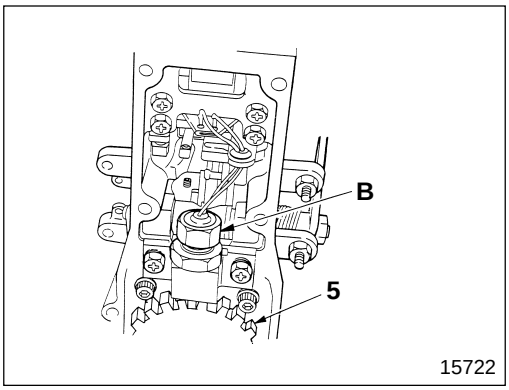
The linear DC motor **7** moves the coil assembly **8** vertically in accordance with signals from the engine electronic control unit. Via the link **6**, this movement is transmitted to the control rack **A**, which moves longitudinally to increase and decrease the fuel quantity.

● Control rack position sensor

The control rack position sensor **2** senses whether the control rack **A** is moved to the correct position by the linear DC motor **7**. In the event of a discrepancy between the actual control rack position and the target control rack position (this is determined by the engine control unit), the control unit instructs the linear DC motor to perform a corrective movement.

● **Emergency engine stop lever**

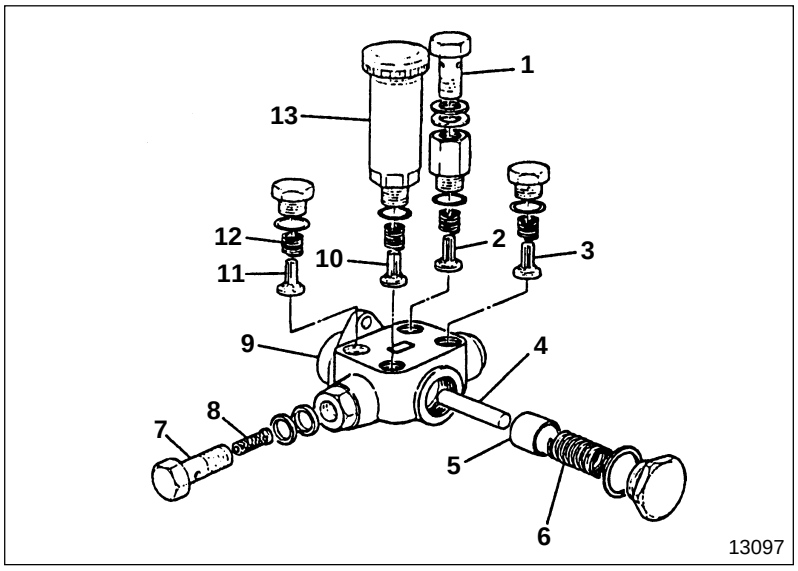
The emergency engine stop lever **4** is connected to the link **6**. Via a cable, it enables the link to be moved from the driver's seat. In the event of a system fault that prevents the engine from being stopped normally, operation of the emergency engine stop lever forces the control rack **A** to move to the position at which fuel injection is terminated. This operation takes place irrespective of the position of the linear DC motor **7**.



● **Backup engine speed sensor**

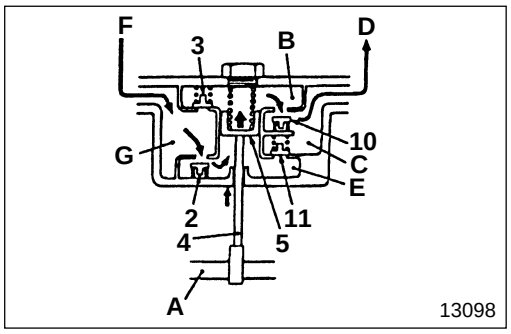
The backup engine speed sensor **B** is fitted inside the governor. It converts the rotation speed of the sensing gear **5** into electric signals and feeds the signals to the engine electronic control unit to provide an indication of the engine speed.

Feed Pump

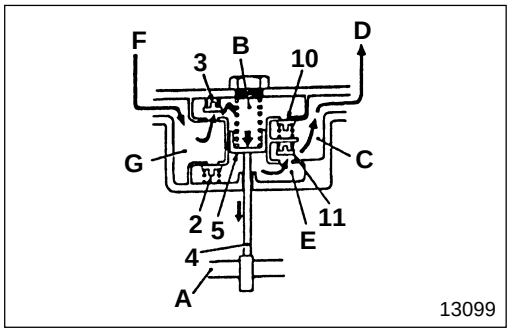


1 Eye bolt at fuel outlet
2 Check valve
3 Check valve
4 Push rod
5 Piston
6 Piston spring
7 Eye bolt at fuel inlet
8 Gauze filter
9 Feed pump housing
10 Check valve
11 Check valve
12 Check valve spring
13 Priming pump

- The feed pump is a double-action type pump which, with four check valves operating, sucks and discharges fuel during both strokes of pistons **5**.
- Push rod **4** makes contact with the injection pump camshaft directly, moving piston **5**.
- Priming pump **13** can be manually operated, when the injection pump is not operating, to suck up fuel and thus can be used for air bleeding.
- Mesh filter **8** eliminates large foreign particles from the fuel sucked up from the fuel tank to prevent clogging of the feed pump. This mesh filter must be cleaned with diesel fuel periodically.

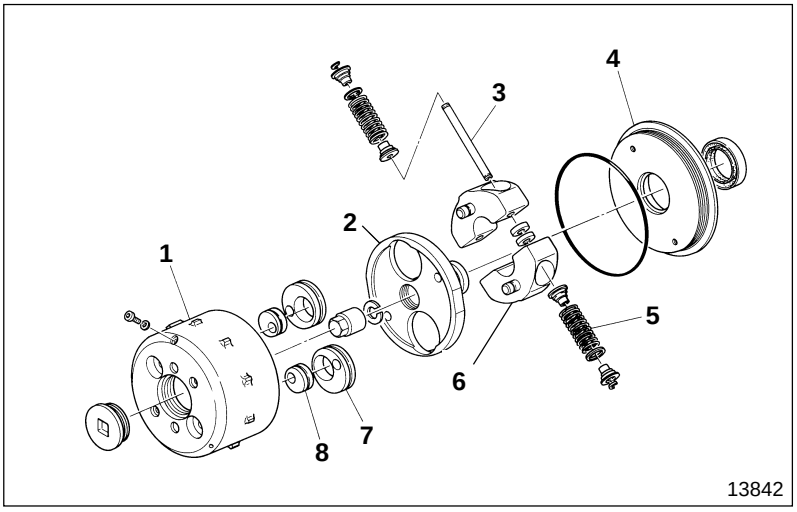


The rotation of injection pump camshaft **A**, pushes up push rod **4** and piston **5**, and the pressure in inner chamber **B** increases. This closes check valve **3**, and check valve **10** opens to let the fuel in inner chamber **B** flow through outer chamber **C** to fuel filter **D**.
When the pressure in inner chamber **E** decreases, check valve **11** closes, and check valve **2** opens to let fuel flow from fuel tank **F** through outer chamber **G** to inner chamber **E**.



When injection pump camshaft **A** rotates further, it pushes down push rod **4** and piston **5**, and the pressure in inner chamber **E** increases. This closes check valve **2**, and check valve **11** opens to let the fuel in inner chamber **E** flow through outer chamber **C** to fuel filter **D**.
When the pressure in inner chamber **B** decreases, check valve **10** closes, and check valve **3** opens to let fuel from fuel tank **F** flow through outer chamber **G** to inner chamber **B**.

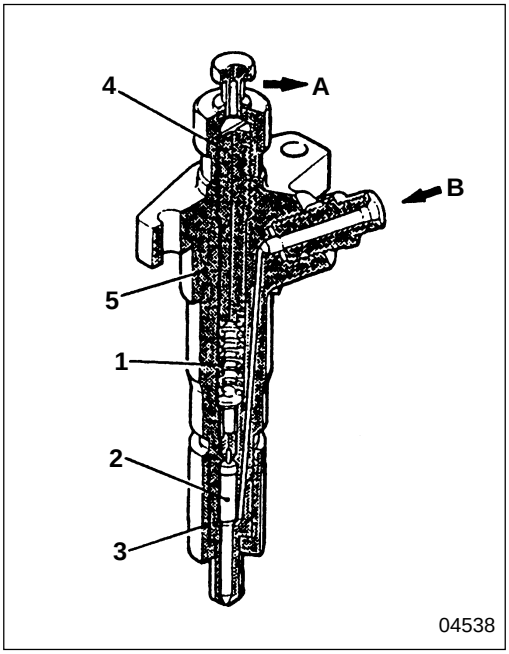
Automatic Timer



1 Timer housing
2 Timer holder
3 Pilot pin
4 Cover
5 Timer spring
6 Flyweight
7 Eccentric cam (Large)
8 Eccentric cam (Small)

- The mechanical type automatic timer changes fuel injection timing automatically when the engine revolution reaches the specified rate.
- The automatic timer controls the retard of fuel injection timing. The pre-stroke control unit controls the advance of fuel injection timing.

Injection Nozzle



1 Nozzle spring
2 Needle valve
3 Nozzle
4 Adjusting screw
5 Nozzle holder

A : Excess fuel
B : Supply of fuel

Fuel delivered from the injection pump enters the nozzle holder and, when the specified pressure is reached, the fuel pressure overcomes the repercussive force of the nozzle spring to push out the needle valve, allowing fuel to spray out the opening at the tip of the nozzle into the cylinder.
Part of the high-pressure fuel lubricates the needle valve and returns through the fuel return pipe to the fuel tank.

TROUBLESHOOTING

Fault Diagnosis Function

- While the starter switch is in the ON position, the fault diagnosis function continuously monitors relevant sensors for faults.
  In the event that a fault is detected, the function illuminates a warning lamp (red or orange) in the meter cluster to alert the driver, memorizes the location of the fault, and switches to a backup mode.
- The memorized fault location can be read as a diagnosis code using an Multi-use tester II or the diagnosis switch.

Warning lamp illumination

	(Orange)	(Red)
1. Safety-critical error (vehicle must not be driven)	OFF	ON
2. Non-safety-critical error (vehicle can be driven despite poor control feeling)	ON	OFF

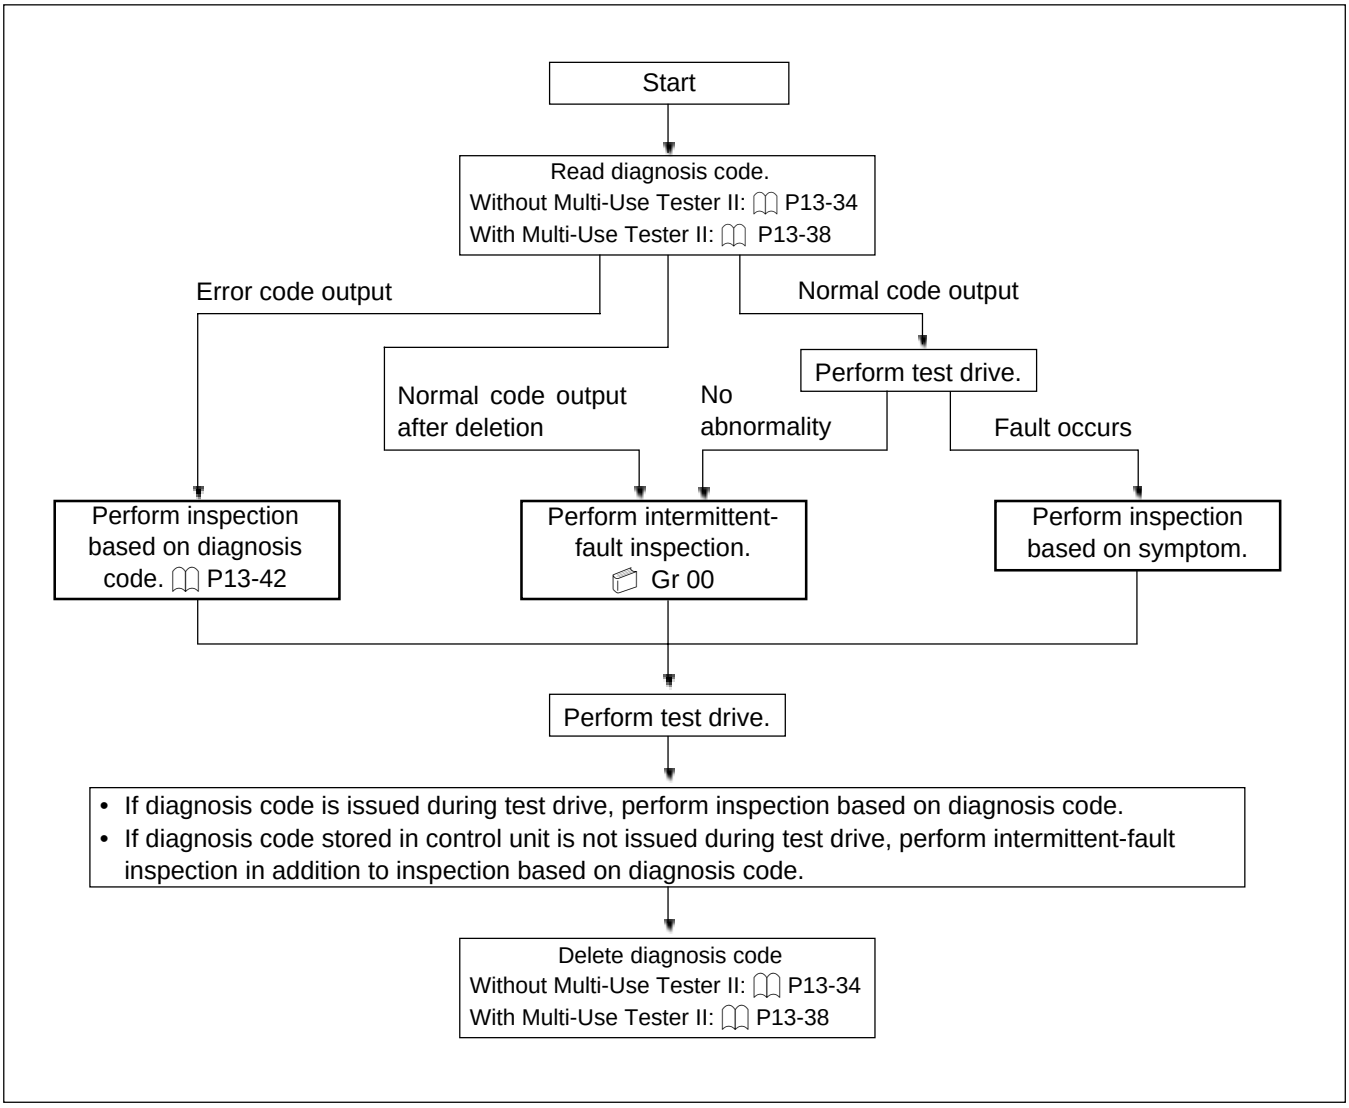
CAUTIONS ⚠

- **The fault diagnosis function requires a battery voltage of 12 V or higher.**
- **In the event of fault detection, check the harnesses and connectors for looseness. Before undoing any connector, turn the starter switch to the LOCK position and wait for 20 seconds.**
- **After rectifying a fault, delete the fault code using the Multi-use tester II or memory clear switch.**
- **As a general rule, inspections should be performed with the starter switch in the LOCK position. If any inspection requires that the starter switch be in the ON position, be careful to avoid short circuits between connector terminals and with the vehicle body.**
- **All component resistances shown in this manual assume a temperature range of 10 to 35°C {50 to 95°F}. In practice, component values may not comply with standard values owing to temperature effects and/or to inaccuracy in the test instrument.**
- **After the rectification of a fault, the system's ability to return to normal operation automatically depends upon the diagnosis code, i.e., the fault location. When the system returns to normal operation, the warning lamp goes out.**
- **When the system returns to normal operation after the rectification of a fault, the diagnosis code remains stored in engine control unit.**

Inspection Procedure

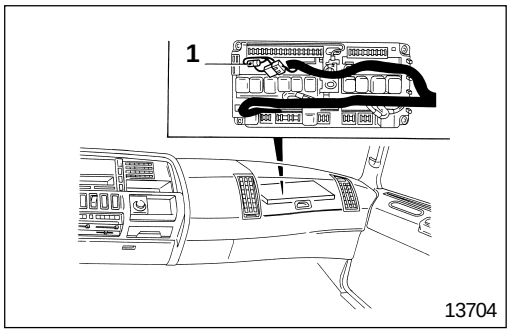
Inspection of the electronic governor and prestroke control injection pump system can be performed most effectively using an Multi-Use Tester II. Types of system inspection can, in accordance with fault systems and diagnosis codes, be broadly classified as follows:

- Inspections based on diagnosis codes stored in the control unit
- Inspections based on symptoms
- Inspections of intermittent faults



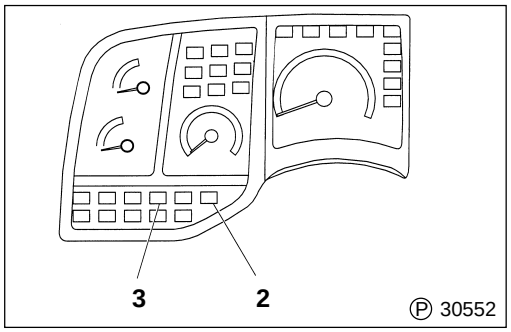
READING AND ERASING DIAGNOSIS CODES

Without Multi-Use Tester II

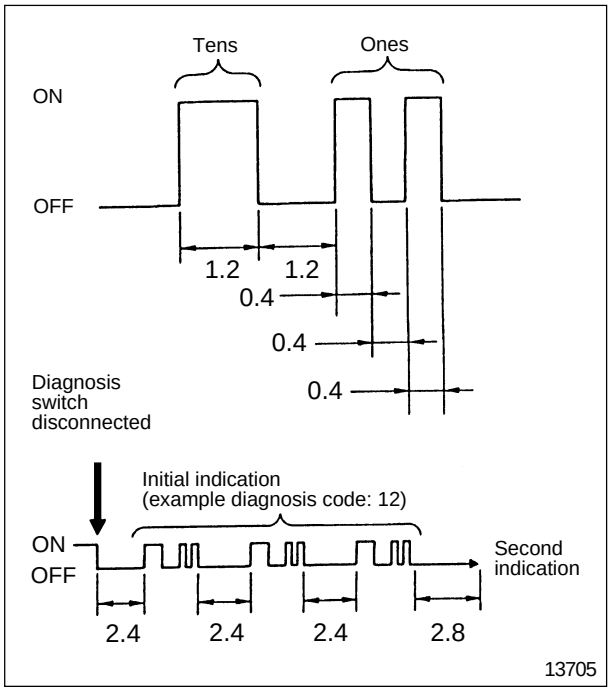


Current diagnosis code

- Turn ON the starter switch.
- Disconnect the diagnosis switch **1**.

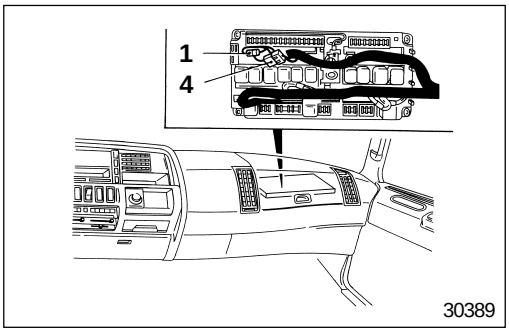


- The diagnosis code will be indicated by flashes of the warning lamp (orange) **2** or warning lamp (red) **3**.



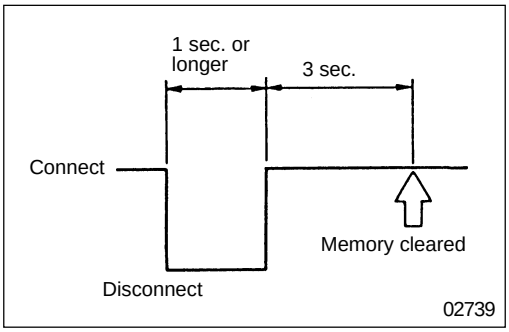
Diagnosis code indication

- Diagnosis codes are indicated by the numbers and durations of the warning lamp flashes.
  - Flashes for units of ten and units of one have different lengths, as follows:
    Units of ten: 1.2 seconds
    Units of one: 0.4 second
  - For each diagnosis code, units of ten are given first, followed by units of one. For a code that has no units of ten, only units of one are given.
- Each diagnosis code is indicated three times. If there are no new codes, the sequence is then repeated from the beginning with each code indicated three times.
- When the diagnosis switch **1** is connected, the control unit immediately stops the indication of codes.



Past diagnosis codes

With the diagnosis switch **1** disconnected, disconnect the memory clear switch **4** after reading the current diagnosis code(s). The warning lamp will begin to flash again, this time to indicate any past diagnosis code(s). Verify the fault location in accordance with the code(s).



Diagnosis code erasing

To erase all stored diagnosis codes from the control unit, disconnect and reconnect the memory clear switch **4**.

CAUTION

- **Stored codes are cleared only by disconnection and reconnection of the memory clear switch 4.**
- **To prevent the memory contents from being cleared after the indication of stored codes, turn OFF the starter switch with the memory clear switch 4 disconnected then connect the memory clear switch.**

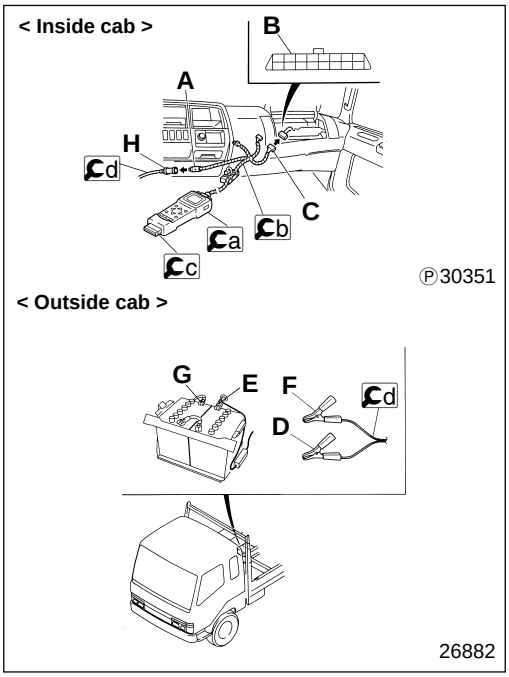
Connecting the Multi-Use Tester II

- Turn the starter switch to the LOCK position.
- Connect the b MUT Communication Harness to the a Multi-use tester II, and insert the c ROM Pack.
- Plug connector **A** into the cigarette lighter socket.
- Fit connector **C** onto MUT connector **B** (16-pin) in the relay box.

NOTE

Instructions for operation of the Multi-use tester II are given in the separate
Multi-Use Tester II Reference Manual.



- To verify the service data “START SIG”, connect the Multi-Use Tester II as follows:
- Turn the starter switch to the LOCK position.
- Connect the b MUT Communication Harness to the a Multi-Use Tester II, and insert the c ROM Pack.
- Attach the (+) clamp **D** (red) of the d Battery Clamp Harness to the battery’s (+) terminal **E**. Attach the (–) clamp **F** (black) of the d Battery Clamp Harness to the battery’s (–) terminal **G**.
- Fit the connector **A** into the socket **H** of the d Battery Clamp Harness.
- Fit connector **C** onto MUT connector **B** (16-pin) in the relay box.

CAUTION ⚠

Connect the (+) clamp D (red) of the b Battery Clamp Harness before connecting the (–) clamp F (black).

Current diagnosis codes
- Turn the starter switch to the ON position.
- Determine the fault location(s) in accordance with the Multi-Use Tester II diagnosis code(s).

SERVICE PROCEDURES USING MULTI-USE TESTER II

Service operations can be performed most effectively using the following Multi-Use Tester II functions:

● **Reading of diagnosis codes**

Using the diagnosis code function, it is possible to read diagnosis codes stored in the control unit.

● **Eraser of diagnosis codes**

By selecting the diagnosis code eraser function from the special function menu, it is possible to erase diagnosis codes stored in the control unit.

● **Indication of service data**

When required for service operations, data in the control unit's random-access memory can be displayed as numeric values or graphs.

ON-VEHICLE INSPECTION AND ADJUSTMENT

Checking and Adjusting Injection Timing

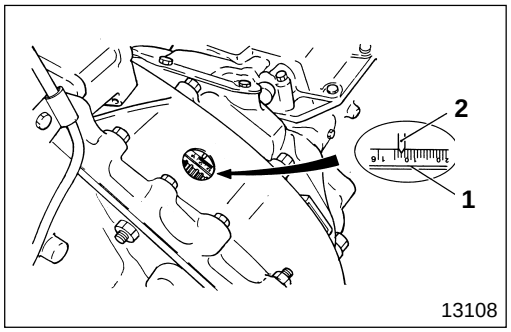
Service standards

Location	Maintenance item	Standard value	Limit	Remedy
–	Fuel injection timing (BTDC)	2˚±0.5˚	–	Adjust

Tightening torque

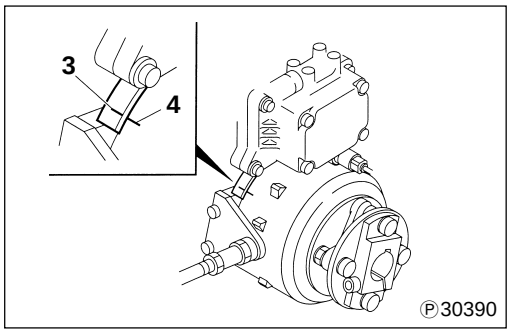
Unit: N·m {ft.lbs., kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
5	Adjusting bolt	59 to 64 {43 to 47, 6 to 6.5}	–

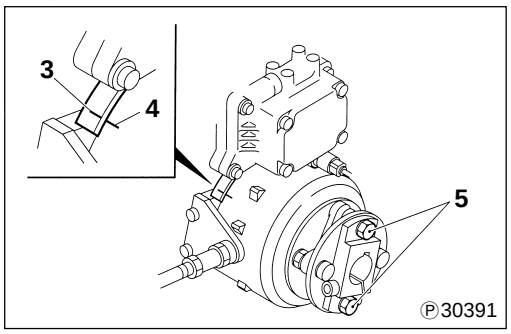


[Inspection]

- Turn the crankshaft more than 180° in the direction of engine rotation. Align the correct timing degree mark **1** on the flywheel with pointer **2** on the flywheel housing to show the standard fuel injection timing.



- When pointer **3** on the injection pump and mark **4** on the automatic timer align, the fuel injection timing is standard.
- If the fuel injection timing is not standard, adjust as follows.



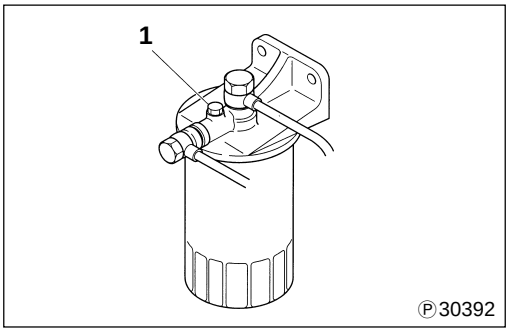
[Adjustment]

- Loosen adjusting bolts **5** and turn the automatic timer to align pointer **3** and mark **4**.
- Tighten adjusting bolts **5** at specified torque.
- Reinspect the fuel injection timing.

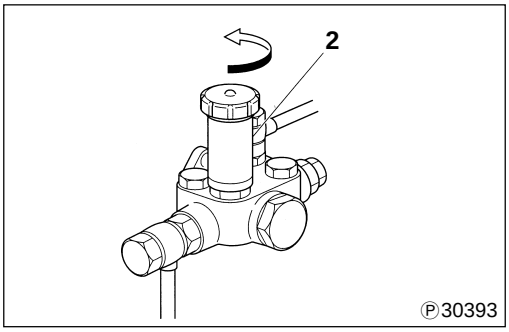
CAUTION ⚠

Do not loosen any bolts other than adjusting bolts 5.

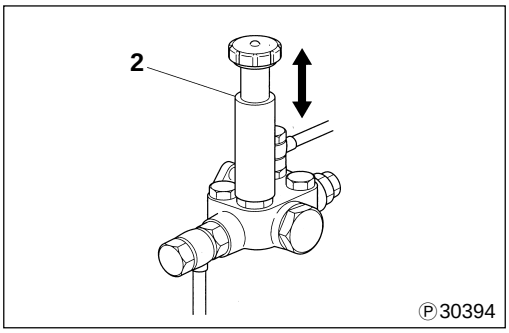
Bleeding Air from Fuel System



- Loosen the fuel filter air plug **1**.



- Turn the priming pump knob **2** counterclockwise until it pops up.
- Move the priming pump knob **2** up and down to feed fuel through the fuel filter.
- When fuel emerging from the fuel filter air plug **1** no longer contains air bubbles, tighten the air plug securely.

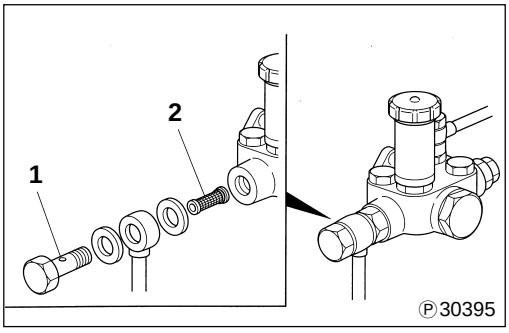


- Move the priming pump knob **2** up and down five or six more times. Then, press the knob down and screw it clockwise to lock it in position.
- Wipe up all spilled fuel, then start the engine.
- Check that no fuel leakage occurs.

WARNING⚠

- **Be sure to wipe up all spilled fuel. Unless it is wiped up, it could catch fire.**
- **Fuel is highly flammable. Keep it away from flames and sources of heat.**

Cleaning Mesh Filter



- Remove the eyebolt **1** from the suction port side **A** of the fuel feed pump.
- Remove the mesh filter **2** from the eyebolt **1**.
- Clean the mesh filter **2** in diesel fuel.
- Refit the mesh filter **2** and eyebolt **1** in the opposite order to that in which they were removed.
- Bleed all air out of the fuel system. 🕮 P13-47
- Start the engine and check that no fuel leakage occurs.

WARNING⚠

- **To minimize the risk of fire, wipe up any spilled fuel.**
- **Fuel is highly flammable. Keep it away from flames and sources of heat.**
- **After refitting the mesh filter, check that no fuel leakage occurs.**

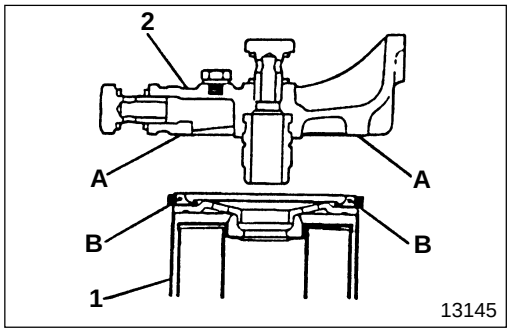
WARNING

- **Fuel is highly flammable. Keep it away from flames and sources of heat.**
- **To minimize the risk of fire, wipe up any spilled fuel.**

[Installation]

WARNING

Use of an unsuitable fuel filter 1 can lead to fuel leaks and fires. Be sure to use a genuine filter.



13145

- To fit the fuel filter **1**, turn it until the gasket **B** touches surface **A** of the fuel filter head **2**. Then, tighten the filter by 1 to $1\frac{1}{8}$ turn. Be sure to turn the filter by hand.
- Bleed all air out of the fuel system. P13-47

WARNING

After fitting the fuel filter 1, start the engine and check that no fuel leakage occurs. Any leaking fuel could cause a fire.

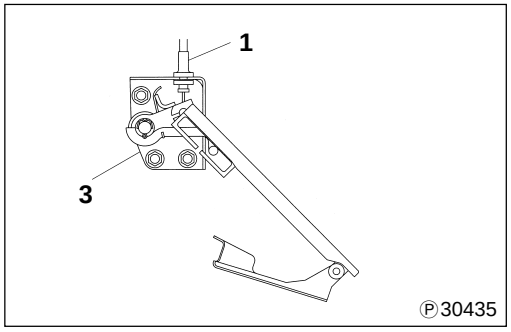
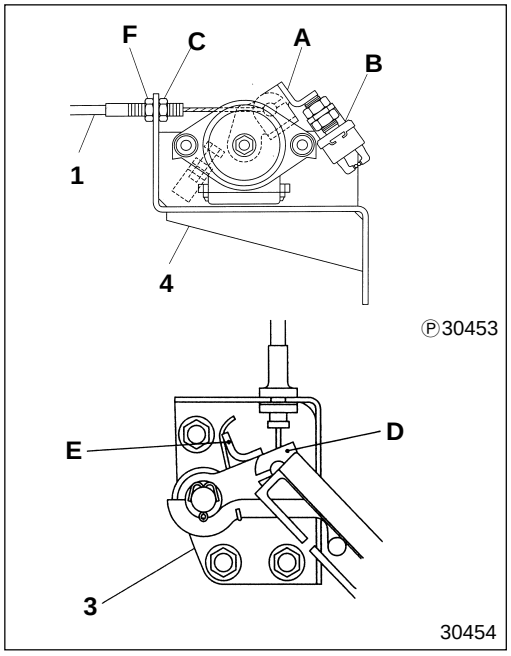
		Sensor I: ⑤ – ⑥	When there is conduction between the accelerator switch terminals ① and ②  31018	1.00±0.2 V	—	Adjust or replace

◆ Service procedure

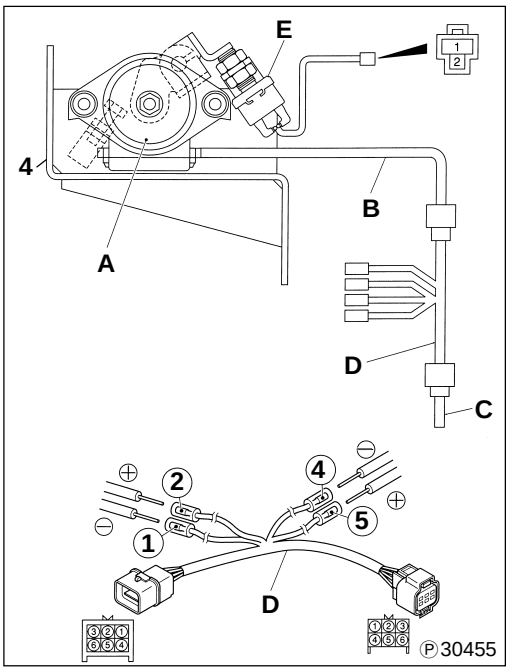


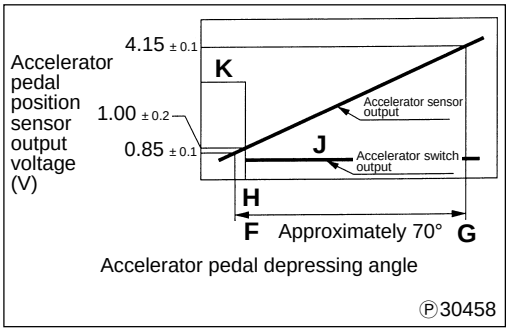
1 **Installation of the accelerator control cable**

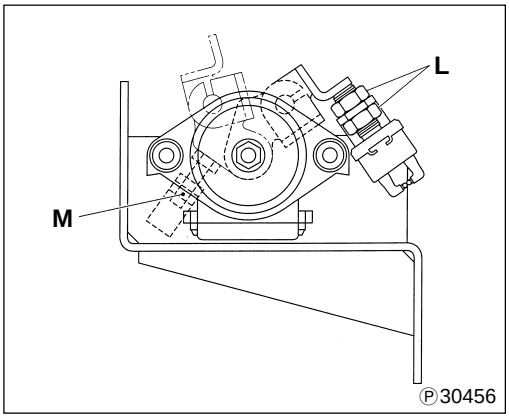
- Install accelerator control cable **1** to accelerator link assembly **3**.



- Install the other end of accelerator control cable **1** to lever **A** of the accelerator pedal position sensor **4**.
- Check that lever **A** of the accelerator pedal position sensor **4** is completely pushed down by accelerator switch **B**.
- Stretch the cable until lever **D** of the accelerator link assembly **3** meets stopper **E** using nut **C** of the accelerator control cable **1** and secure with nut **F**.







4 Inspect the accelerator pedal position sensor

- Disconnect connector **B** of accelerator pedal position sensor **A** from harness **C** on the cab side. Prepare inspection harness **D,** and connect it between the above two connectors.
- Disconnect the harness of accelerator switch **E**.
- Turn the starter switch ON.
- Inspect the output voltage of the accelerator pedal position sensor **A** and accelerator switch **E** as shown in the following chart and adjust as needed.

Item	Connector terminal

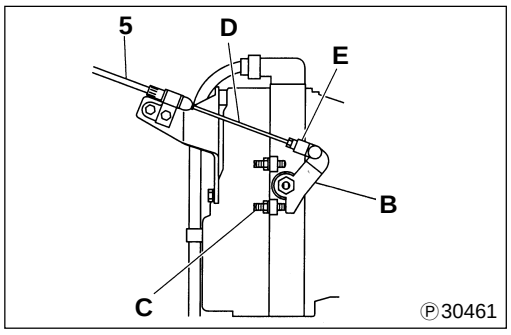
5 **Installation of the emergency engine stop cable**

- Install the push button **A** side of the emergency engine stop cable **5** and push the stop button in.



- With the stop lever **B** of the governor making contact with the stopper bolt **C**, install the cable and adjust clevis **E** such that the inner cable of the emergency engine stop cable is not loose.
- After the installation, start the engine. Check that pulling the stop button stops the engine.

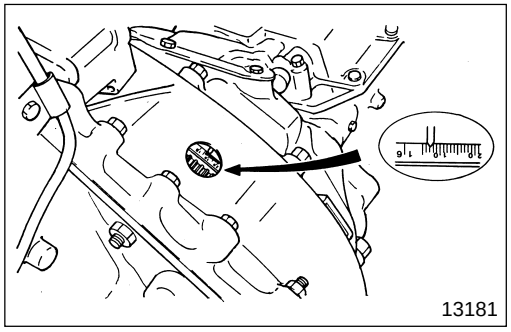
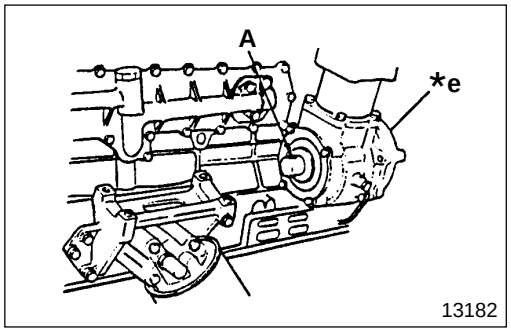
◆ Service procedure

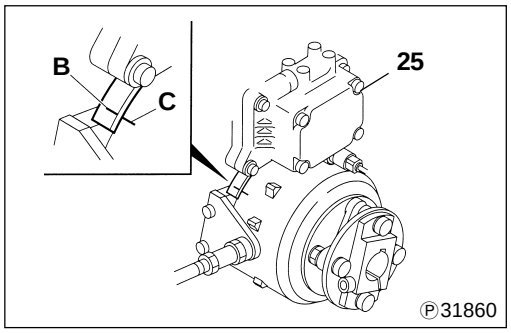
25 Installation of Injection pump assembly



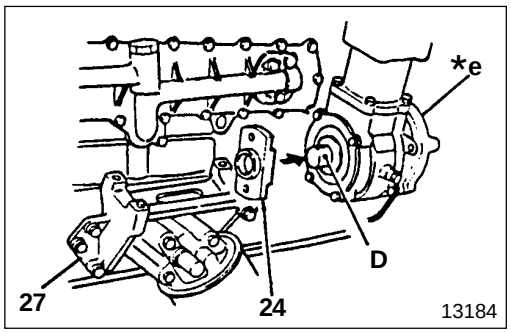
- Turn the engine and adjust No.1 cylinder piston to the specified fuel injection timing position.



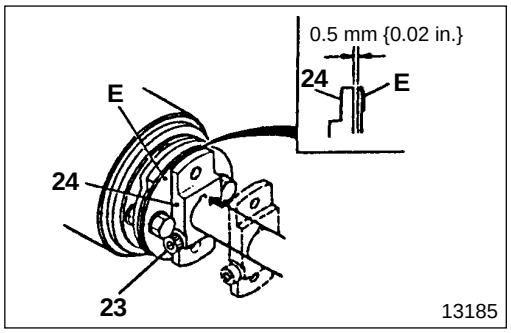
- In this state, make sure that keyway **A** in the crankshaft of air compressor ***e** faces upward.
- If keyway **A** is not facing upward, turn the engine crankshaft by one turn.



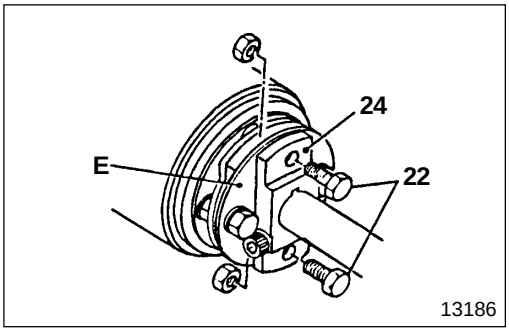
- Align pointer **B** on injection pump assembly **25** with mark **C** on the automatic timer.



- Install driving coupling **24** to crankshaft **D** of air compressor ***e** and place the driving coupling on the air compressor side.
- Install injection pump assembly **25** on injection pump bracket **27**.

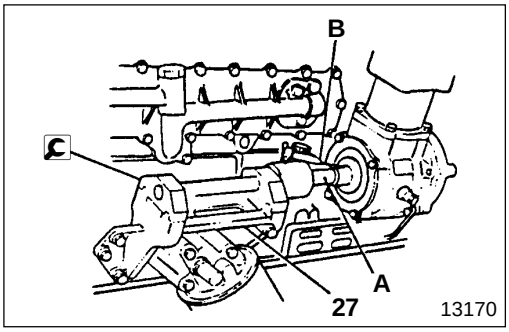


- Move driving coupling **24** to adjust the clearance between the driving coupling and coupling plate **E** as illustrated, then tighten cotter bolt **23** at specified torque.



- Attach driving coupling **24** and coupling plate **E** using bolts **22** and tighten the bolts temporarily.

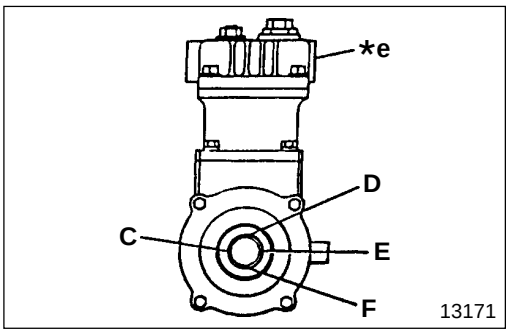
- In this state, adjust the fuel injection timing.
  Adjustment of fuel injection timing : P13-46
  After adjusting the fuel injection timing, tighten bolts **24** at specified torque.



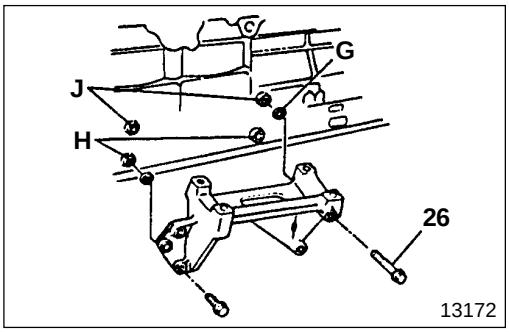
27 Injection pump bracket

[Inspection]

- Attach dial gauge **B** to arbor **A** of injection pump centering tool and adjust to gauge to zero setting.



- Slide dial gauge **B** toward air compressor ***e** and measure the eccentricity of crankshaft **C** against arbor **A** at points **D**, **E** and **F**.
- If the measured value is higher than the standard value, adjust as follows.



[Adjustment]

- When the measured value at point **E** is higher than the standard value: Insert shims **G** into four points equally.
- When the measured value at point **D** is higher than the standard value: Insert shims **G** into lower side **H**.
- When the measured value at point **F** is higher than the standard value: Insert shims **G** into upper side **J**.

CAUTION

Insert shims G observing the following conditions:

- **Number of shims per point is three or less.**
- **The same number of shims should be used for the front and the rear.**
- **The difference in number of shims used for bottom and top is none or one.**

- Tighten bolt **26** at specified torque, then reinspect.

- **Never change the combination of needle valve 11 and nozzle 12 for each cylinder.**
- **Be sure to protect all openings by covering them after removal of hoses and pipes because the engine performance is adversely affected if dirt and foreign particles enter injection nozzle assembly 5.**

NOTE

- **Remove carbon deposits and clean injectlon nozzle assembly 5 before working on it, then test the injection pressure and jet spray condition, and check for fuel leakage before disassembly. If no fault is found, do not disassemble.**
- **After installing injectlon nozzle assembly 5, tighten the two bolts 4 alternately.**

◆ Service procedure

● Inspection before disassembly

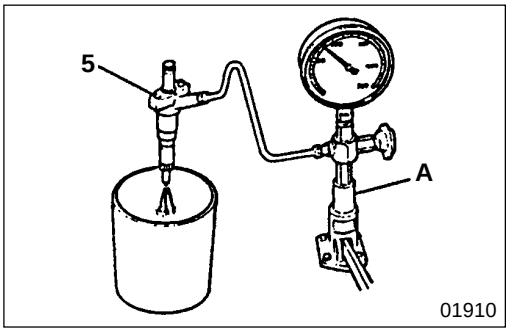
Attach injection nozzle assembly **5** to nozzle tester **A**, and conduct the following inspection.

WARNING ⚠

Never touch the spray from the nozzle or let your hands get too close to the spray point during the test.

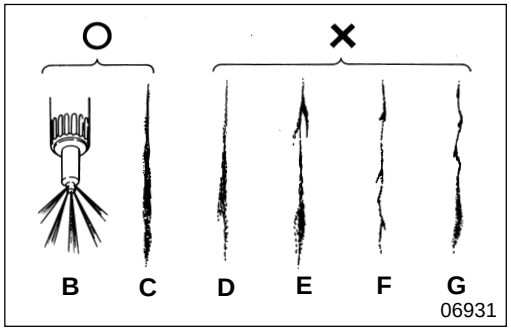
NOTE

Before inspection, bleed the air out in a couple of bursts by pressing nozzle tester A lever.



(1) Valve opening pressure

- Spray continuously with quick lever actions of nozzle tester **A**, one to two seconds per stroke, and measure the pressure that the gauge registers when the pressure is released which will be observed by the sudden movement of the gauge indicator.
- If the measured value deviates from the standard value, disassemble injection nozzle assembly **5** and clean it, then adjust using adjusting screw **7**.
- If the performance cannot reach the standard value even after adjustment, replace injection nozzle assembly **5**.



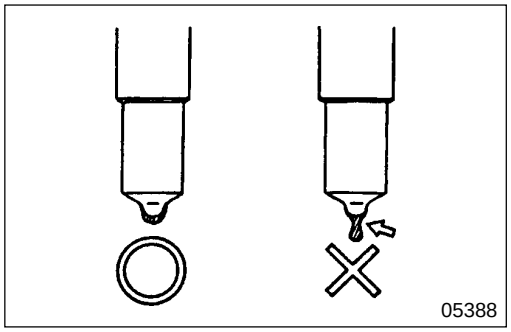
(2) Spray condition

- Spray continuously with quick lever actions of nozzle tester **A**, one to two seconds per stroke.
  - **B** : Even spray from all five orifices (Good)
  - **C** : Even and symmetrical spray (Good)
  - **D** : Asymmetrical spray (Faulty)
  - **E** : Spray direction deviates from the nozzle axis line (Faulty)
  - **F** : Thin and insufficient spray (Faulty)
  - **G** : Irregular spray (Faulty)

- If faulty spray cannot be corrected, disassemble injection nozzle assembly **5** and clean every part and repeat the test.
  If faulty spray still occurs after repeating test, replace the injection nozzle assembly.
- Make sure that there is no post-spray dripping after injection.

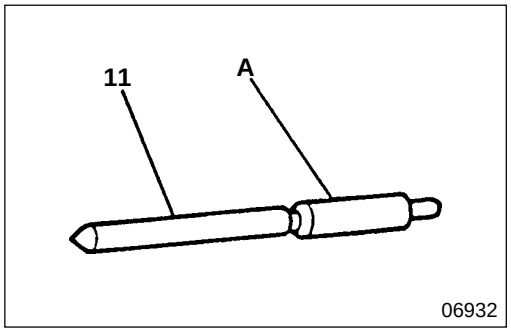
WARNING

Never touch the spray from the nozzle or let your hands get too close to the spray point during the test.



(3) Fuel air tightness and leakage at related contact points

- Raise the interior pressure of the nozzle gradually to the test pressure of 14.7 MPa {150 kgf/cm^2}. Maintaining the pressure, check and see if any fuel seeps out of the nozzle tip within 10 seconds.
- If any fault is found, disassemble injection nozzle assembly **5** and clean every part and repeat the test. If any fault is still found, replace the injection nozzle assembly.

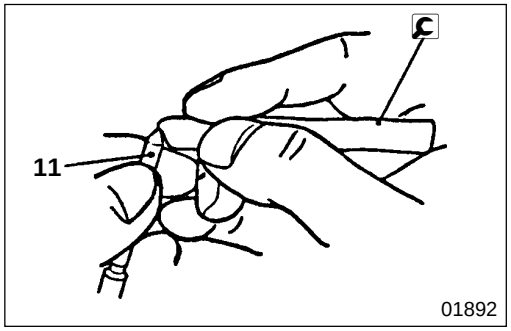


5 Injection nozzle assembly

[Disassembly]

CAUTION

- **Be sure not to touch sliding part A of needle valve 11 with your hands.**
- **Never change the combination of removed needle valve 11 and nozzle 12 for each cylinder.**



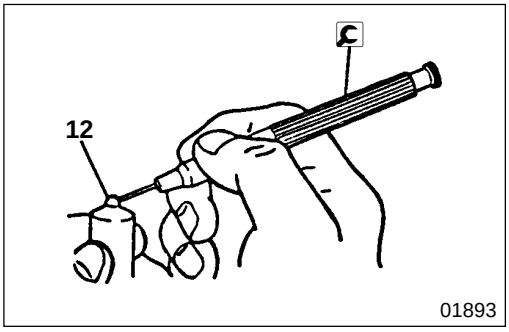
[Cleaning]

Clean needle valve **11** and nozzle **12** with diesel fuel (cleaning solvent).
Remove carbon deposits with cleaning tool in the following manner:

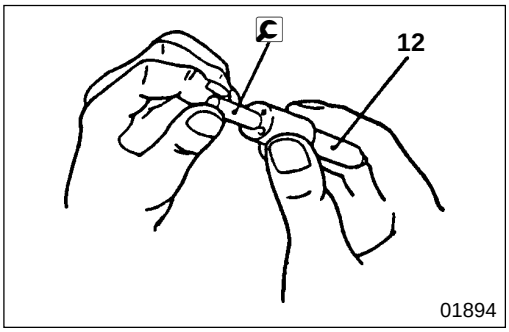
- Clean needle valve **11** by removing carbon deposits from its tip using the cleaning bar of cleaning tool.

CAUTION

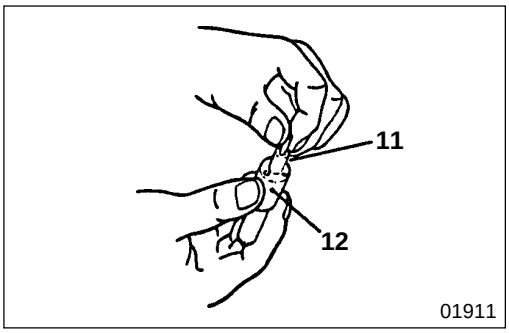
Never use a wire brush or hard steel for cleaning.



- To clean nozzle **12**, remove carbon deposits from the orifices of the nozzle using the needle cleaner of cleaning tool, by inserting it into the orifices and turning it.
  Needle cleaner diameter: ø 0.25 mm {0.0098 in.} or less



- Clean the seat of nozzle **12** using the cleaning scraper of cleaning tool.
- Use FUSO carbon remover to remove hard-to-remove, burnt-on carbon deposits.



[Inspection]

- Immerse needle valve **11** and nozzle **12** in diesel fuel (cleaning solvent) and clean them thoroughly.
- Check and see if needle valve **11** drops by its own weight into the nozzle from the position where a third of its length is pulled out.
  (Repeat this several times rotating the needle valve.)
- If needle valve **11** does not drop smoothly, repeat cleaning and repeat the test. If any fault is still found, replace both the needle valve and nozzle **12** together as a set.

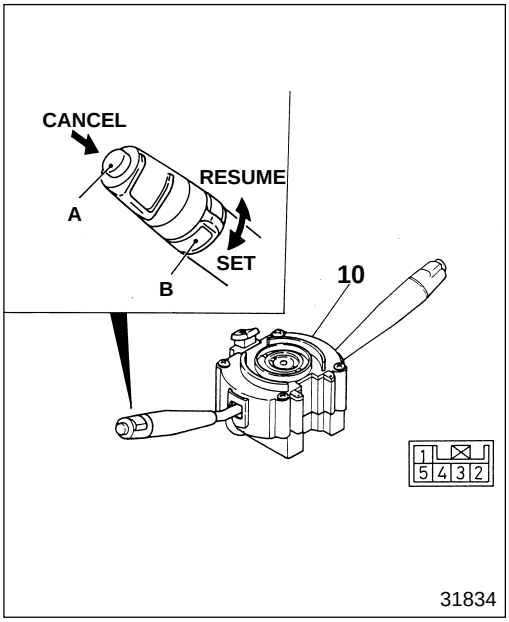
Unit : N·m {ft.lbs, kgf·m}

Location	Part to be tightened	Tightening torque	Remarks
7	Coolant temperature sensor	34±6.9 {25±5, 3.5±0.7}	—
12	Engine speed sensor lock nut	24 to 35 {17 to 26, 2.4 to 3.6}	—

◆ Service procedure



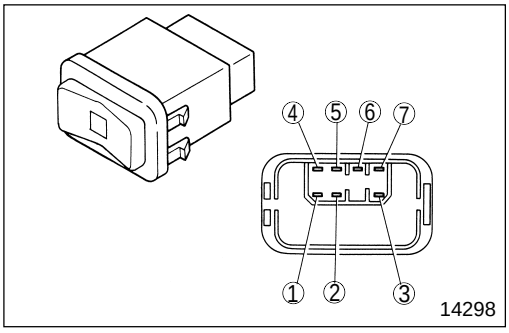
1 **Inspection of the combination switch**

- Check for conduction as indicated in the following chart.

		①	②	③	④	⑤
Set/resume switch and cancel switch	Set		○	○		
	Cancel			○		○
	Off					
	Resume			○	○	

A : Cruise control cancel switch
B : Cruise control set/resume switch
There should be conduction between the ○——○ terminals in the chart.

- If there is a malfunction, replace the combination switch **1**.



2 **Cruise control main switch**

- Check for conduction as indicated in the following chart. There should be conduction between the ○——○ terminals in the chart.
- If there is a malfunction, replace the main cruise control switch **2**.

	①	⑥	⑤	④	⑦	LED (Operation indicator)	③
ON	○	○	○	○	○	○	○
N (Neutral)		○		○

3 **16** **Inspection of the exhaust brake relay < M/T >, accelerator relay < A/T >, and cruise control main relay**

- Check for conduction as indicated in the following chart.

	①	②	③	④	⑥
Not Energized	○		○		
		○			○
Energized	○			○	
		○			○

There should be conduction between the ○——○ terminals in the chart.
Apply 12 V DC between ⊕——⊖ terminals.

- If there is a malfunction, replace the relay.

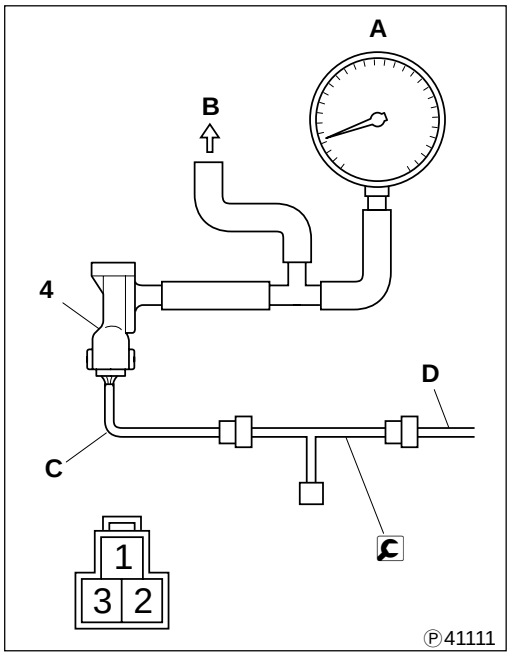
4 Checking Boost Pressure Sensor

< Checking by use of Multi-Use Tester II >

P13-40

NOTE:

The boost pressure checking conditions differ between when the boost pressure is checked by use of the Multi-Use Tester II and when it is checked without use of the Multi- Use Tester II. So the standard values also differ.



< Checking without use of Multi-Use Tester II >

- Disconnect the harness **C** of the boost pressure sensor from the chassis side harness **D** and connect the inspection harness between them.

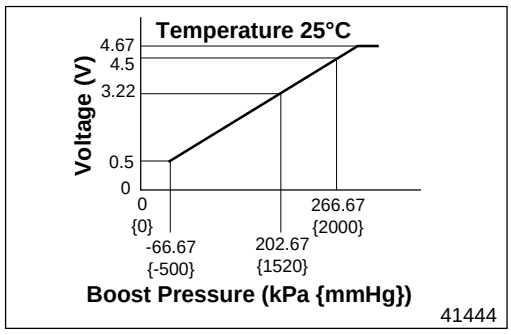
Tool Name and Shape	Part No.
Inspection Harness  02806	MC854336

- Mount pressure gauge **A** for measurement of the boost pressure.
  B: To inlet manifold
- Set the starter switch to ON.
- Measure the output voltage of the boost pressure sensor **4** according to the following table.

Item	Connector Pin		
	① Power (+)	② GND (-)	③ Output (+)
Power voltage	○	○	
* Output voltage (Refer to the output characteristics shown at left.)		○	○

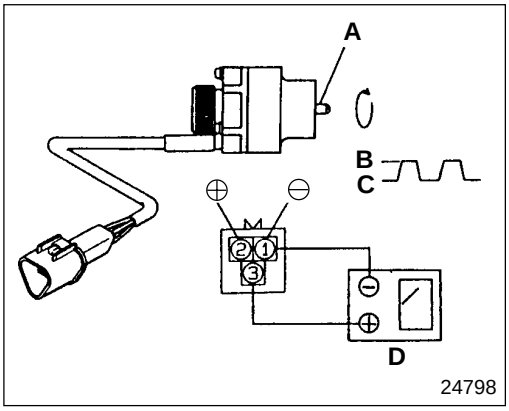
*: Start the engine before measurement.

Output Characteristics



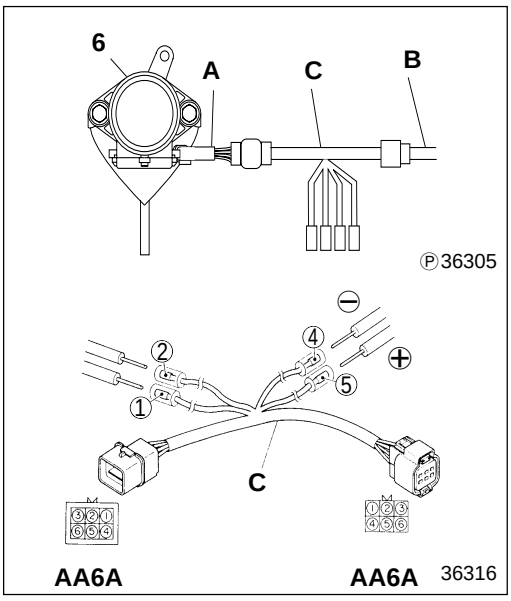
Standard Value	② - ③	5 V
	① - ②	0.5 V/–34.3 kPa {–10.0 in. Hg, –255 mmHg}
		1.86 V/33.7 kPa {9.84 in. Hg, 250 mmHg}
		3.22 V/98.7 kPa {29.1 in. Hg, 740 mmHg}
		4.5 V/163.7 kPa {48.4 in. Hg, 1230 mmHg}

- If the results of the above mentioned checks show any deviation from the standard values, replace the boost pressure sensor **4**.



5 Inspection of the vehicle speed sensor

- Apply 12 V DC between terminals ① and ②, and slowly turn portion **A** of the vehicle speed sensor **5**.
- Measure the maximum value (high pulse voltage **B**) and the minimum value (low pulse voltage **C**) generated between terminals ① and ③ under the above conditions.
  D : Tester
- If the measured value is outside of the standard range, replace vehicle speed sensor **5**.

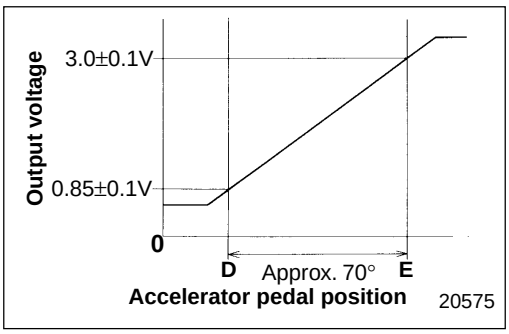


6 Inspection of work load sensor

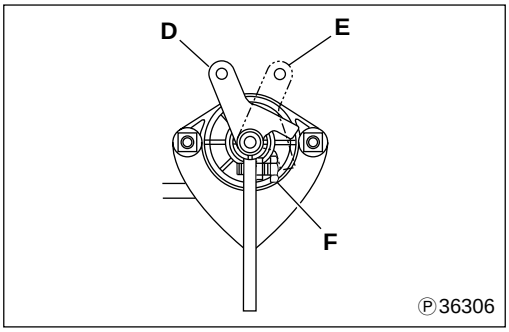
- Disconnect the harness **A** for work load sensor **6** from the cab side harness **B**, and connect a separately prepared inspection harness **C** between harnesses **A** and **B**.
- Check the output voltage of the work load sensor **6** according to the table below, and adjust it if necessary.

Lever position		AA6A Harneses for work load sensor inspection ④: GND (⊖)	AA6A Harneses for work load sensor inspection ⑤: Output (⊕)
Standard value	***a** Output voltage (idling position)	0.85±0.1V	
	***b** Output voltage (full-load position)	3±0.1V	

⊕ ⊖ show the polarities of tester probes to be connected when measuring output voltage.
***a** : Measure with the accelerator pedal in the idling position
***b** : Measure with the accelerator pedal in the full-load position
D : Idling position
E : Full-load position

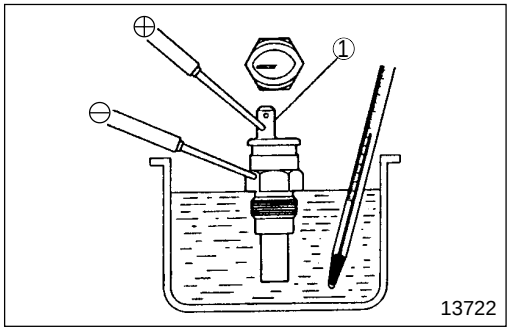


- If the output voltage measurement corresponding to the full-load position deviates from the standard value, adjust it using the full-load stopper bolt **F**.



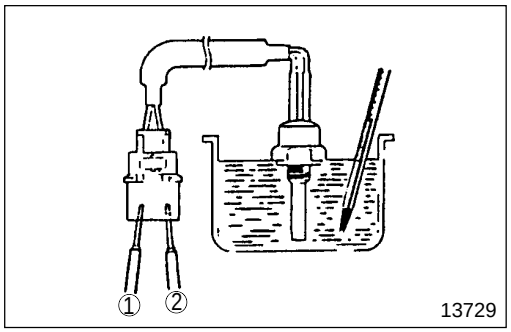
- If the output voltage measurement corresponding to the idling position deviates from the standard value, replace the work load sensor **6**.

INSPECTION OF OTHER DEVICES



7 Inspection of engine coolant temperature sensor

- Put the engine coolant temperature sensor **7** in a container of engine oil.
- Heat the oil to each of the specified temperatures. Stir the oil to ensure that it heats up evenly.
- At each of the specified temperatures, measure the resistance between the terminal ① and body of the engine coolant temperature sensor **7**.
- If the measurements are out of specification, replace the engine coolant temperature sensor **7**.

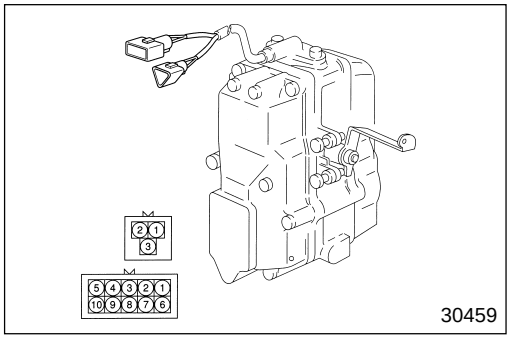


8 Inspection of boost temperature sensor

- Place boost temperature sensor **8** in glycerin in a container.
- Raise the glycerin temperature to the specified values and stir the glycerin.
- Measure the resistance between temminals ① and ②.
- If the measured value deviates from the standard value, replace boost temperature sensor **8**. Gr 15

9 Inspection of control rack position sensor

Perform the following inspections. If any abnormality is evident, have inspection and repair performed by the nearest MFTA Dealer.



● Measurements on connectors

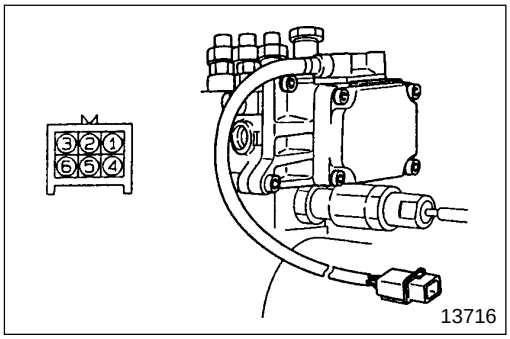
Measure the resistances between the following terminals: 3-pin connector's ③ and 10-pin connector's ④; 10-pin connector's ③ and ⑨; ④ and ⑨.

10 Inspection of pre-stroke actuator

Perform the following inspections. If any abnormality is evident, have inspection and repair performed by the nearest MFTA Dealer.

CAUTION ⚠

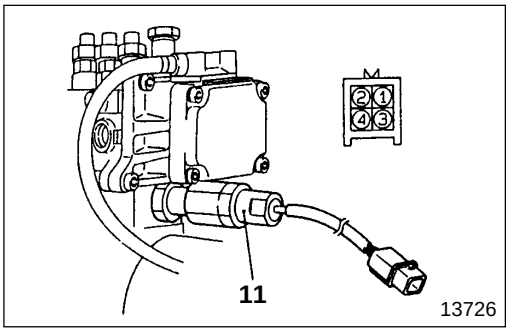
The pre-stroke actuator 10 must be inspected when the engine is cold.



13716

(1) Measurements on connectors

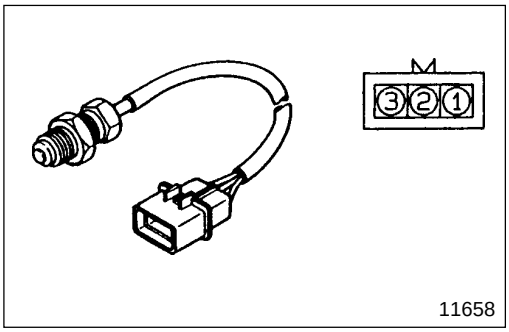
Measure the resistance between terminals ② and ③; ① and ③; ① and ②; ④ and ⑤.



13726

11 Inspection of sub control rack position sensor

- Measure the resistances between the following terminals: ① and ④; ① and ③; ③ and ④.
- If any resistance is out of specification, replace the sub control rack position sensor **11**.
- Have replacement performed by the nearest MFTA Dealer.



11658

12 Engine speed sensor

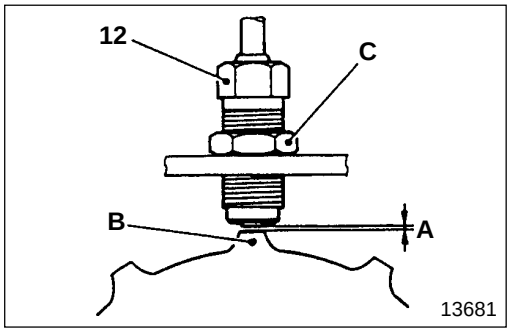
[Inspection]

(1) Main Unit

- Measure the resistance value between terminals ① and ②.
- If the measured value is outside of the standard range, replace the engine speed sensor **12**.

CAUTION ⚠

If the tightening torque of engine speed sensor 12 is insufficient, the signals may not be output correctly. Therefore, check the tightening torque.



(2) Gap of protrusion

If the gap **A** between the engine speed sensor **12** and the protrusion **B** of the timer housing is outside of the standard range, adjust with the following procedure.

[Adjustment]

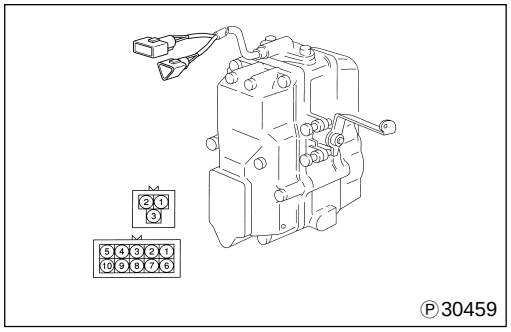
- Adjust by loosening lock nut **C** and turning engine speed sensor **12**.
- After adjustment is complete, tighten lock nut **C** with the specified torque.

CAUTION

If the gap C between the engine speed sensor 12 and the protrusion B of the timer housing is too large, no signals will be output, and if it is too small, the sensor might make contact with the protrusion.

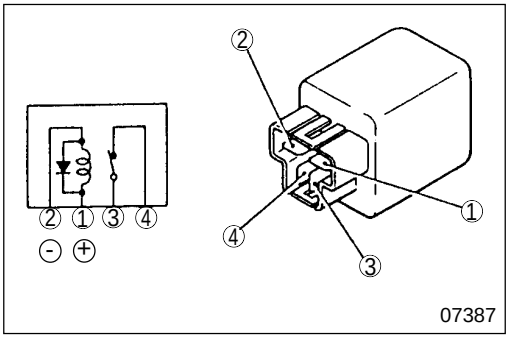
13 Inspection of linear DC motor

Perform the following inspections. If any abnormality is evident, have inspection and repair performed by the nearest MFTA Dealer.



(1) Measurements on connectors

Measure the resistance between terminals ① and ② on each connector.



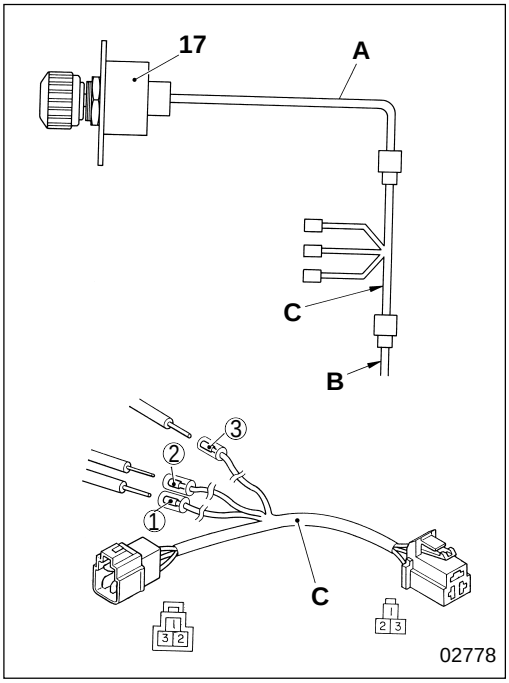
15 Inspection of pre-stroke cut relay (normally-closed type with 4-pin connector)

- Perform continuity checks in accordance with the following table.

	①	②	③	④
Not energized	○	○	○	○
Energized	⊕	⊖	◌	◌

○——○ : Continuity exists between terminals.
⊕——⊖ : Terminals across which 12 V DC is applied
◌- - -◌ : Continuity no longer exists between terminals

- Replace the relay if any abnormality is evident.



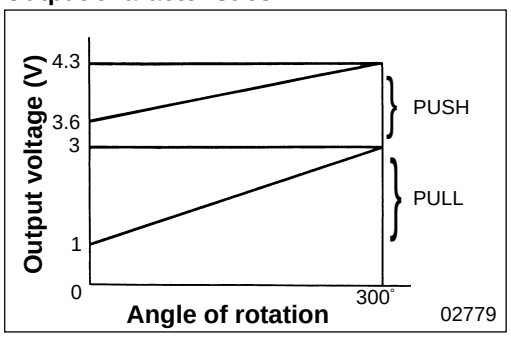
17 Inspection of idling speed adjustment potentiometer

- Disconnect the harness **A** of the idling speed adjustment potentiometer **17** from the cab-side harness **B**. Then, connect an inspection harness **C** between harnesses **A** and **B.** (The inspection harness must be made specially for this procedure.)
- Turn the starter switch to the ON position.
- Check the output voltages of the iding speed adjustment potentiometer **17** in accordance with the following table.

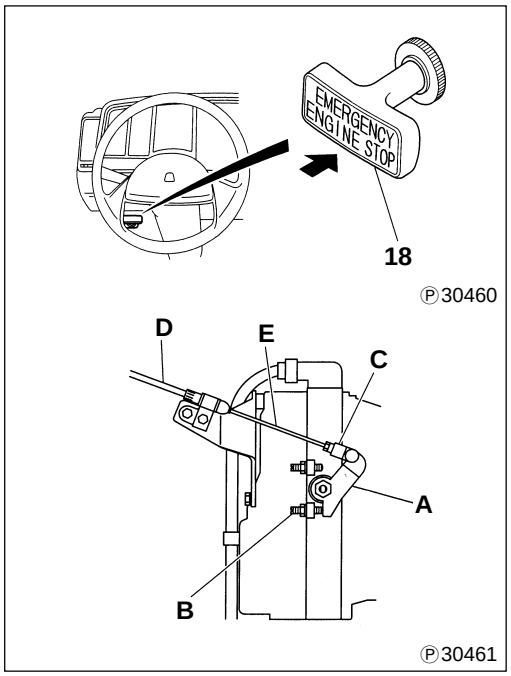
Item	Connector terminal		
	Accelerator pedal position sensor inspection harness		
	①: Power supply (+)	②: GND (–)	③: Output (+)
Output voltage with knob pulled		⊖	⊕
Output voltage with knob pushed			

INSPECTION OF OTHER DEVICES

Output characteristics



- If the output voltages are out of specification, replace the idling speed adjustment potentiometer **17**.



18 **Inspection of the emergency engine stop button**

- Fully press down the emergency engine stop button **18**.
- Check that the stop lever **A** of the governor is in contact with the stopper bolt **B** at this time.
- If it is not in contact, adjust it such that it makes contact by turning crevice **C**.
- Moreover, tighten inner wire **E** of stop cable **D** just enough to prevent it from being slack.

CAUTION ⚠

Be careful not to stretch the inner wire E too much. Doing so can cause the stop lever A not to make contact with the stopper bolt B.

Thermostat **2** is a bottom bypass type that uses wax pellets as its regulating element. As the wax changes its form from solid to liquid according to changes in temperature, the volume of the wax changes. Therefore, the position of the valve, changed by the coolant temperature, regulates the flow of the coolant to the radiator and water pump (bypass side) and controls the coolant temperature.

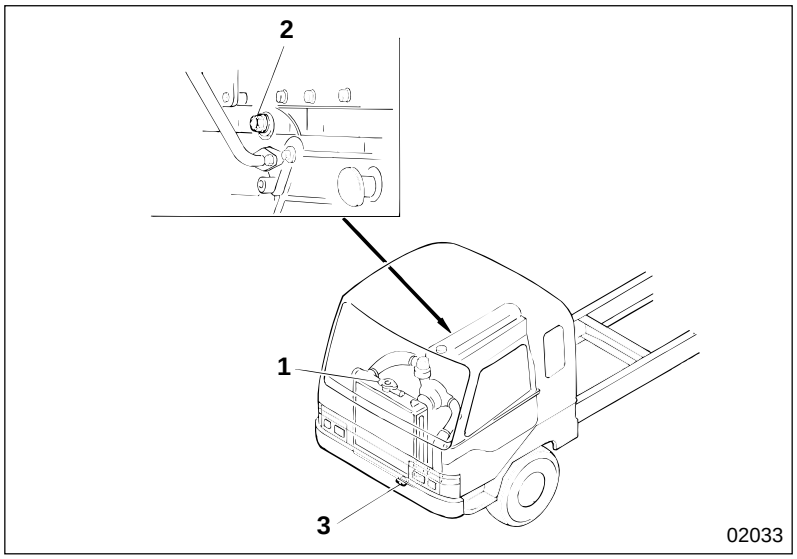
Replacing Coolant and Cleaning Cooling System



1 Pressure cap
2 Crankcase drain plug
3 Radiator drain plug

Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
2	Crankcase drain plug	115 {87, 12}	—

Using the radiator for a long period of time without cleaning it will cause overheating because rust and scale deposits will accumulate inside the cooling system. Periodical cleaning is recommended.

● **Draining coolant**

First loosen pressure cap **1,** to lower the pressure in the cooling system, before draining coolant.

WARNING

- **You must make sure that the engine coolant is cold before draining it so as not to scald yourself.**
- **It is dangerous to open pressure cap 1, when the coolant temperature is high, without taking due care because the hot water would spray out. Be sure to cover the pressure cap with a cloth and loosen slowly to bleed the pressure before opening fully.**

● **Cleaning procedure**

- Keep the coolant temperature at approximately 90°C {194°F} so that the thermostat valve remains open and the coolant continues to circulate in the radiator.
- For the sake of convenience you can raise the coolant temperature quickly by covering the front of the radiator with corrugated cardboard or something similar.
- Set the temperature adjusting lever of the heater controller at maximum so that the coolant can circulate freely in the heater piping area.
- In cases where a great amount of rust has accumulated it often happens that as a result of cleaning the radiator starts leaking. Conduct a thorough check for leakage after cleaning.
- Soft water to be used should have the following properties.

CAUTION

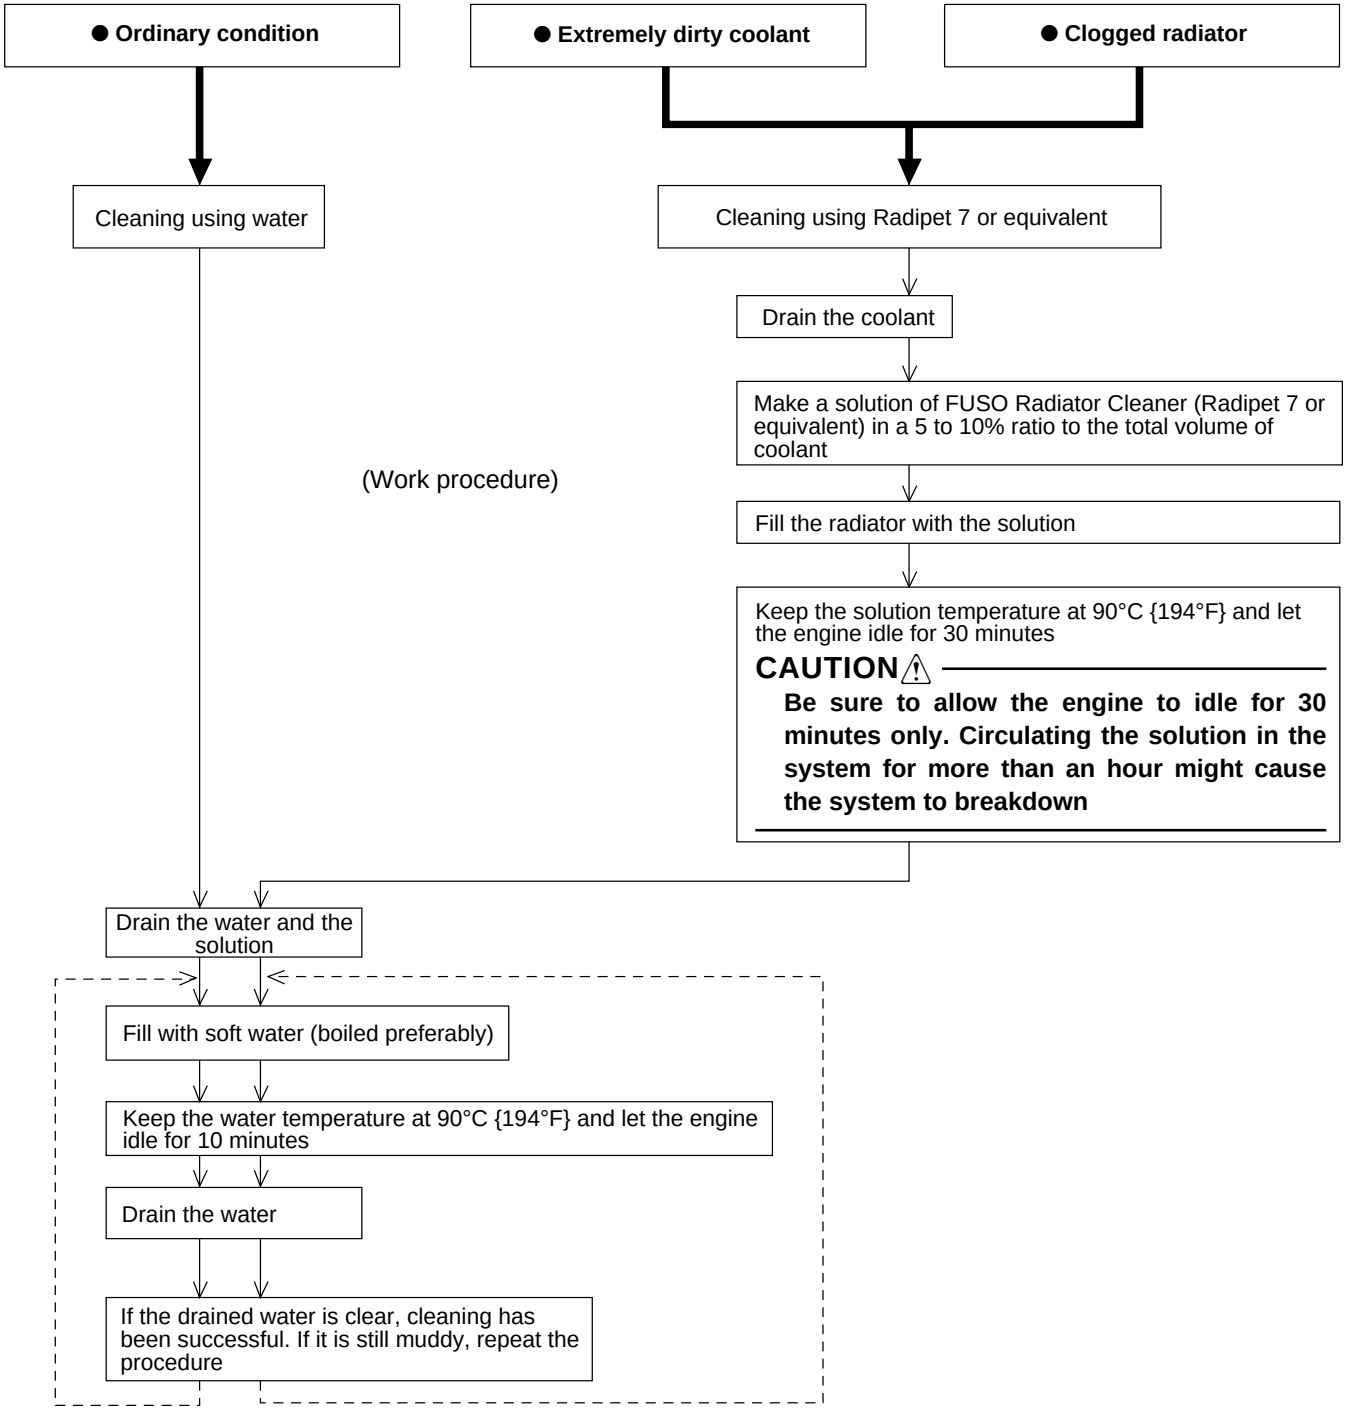
Do not use hard water as it causes scale and rust.

Required properties of soft water

Total hardness	300 ppm or less
Sulfate SO_4^-	100 ppm or less
Chloride Cl^-	100 ppm or less

Total dissolved solids	500 ppm or less
pH	6 to 8

Method of cleaning the cooling system depends on its condition.



DANGER

If FUSO DIESEL LONG LIFE COOLANT solution gets in your eyes accidentally, you must immediately rinse your eyes with copious amounts of water, and be sure to consult a doctor.

WARNING

FUSO DIESEL LONG LIFE COOLANT is inflammable. Do not put it near naked lights.

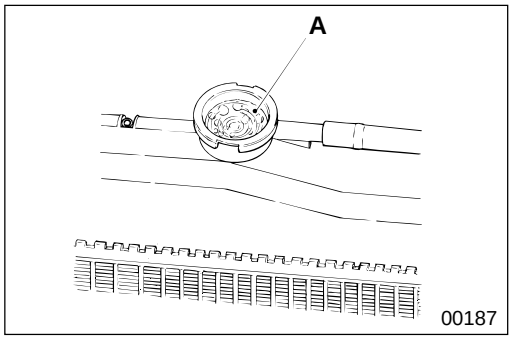
NOTE

- **After cleaning with solution, fill with coolant as quickly as possible.**
- **To prevent freezing of the coolant and corrosion of the cooling system, use specified coolant solution of FUSO DIESEL LONG LIFE COOLANT. (See the Owner's Handbook for use of these materials.)**

Air Bleeding of Cooling System

- Remove the pressure cap and keep the coolant temperature at 90°C {194°F} while letting the engine idle and bleed the air out completely. Keep the temperature adjusting lever of the heater controller at maximum so that the coolant can circulate freely in the heater piping area.
- After completing adequate air bleeding of the cooling system, refill coolant sufficiently enough for the surge tank.

Gas Leakage Test



Air or exhaust gas in the coolant increases corrosion and rusting in the system. Therefore, carry out the following test:

- Remove the surge tank pressure cap and check if the coolant level comes up to the lip of the tank.
- Put the end of the overflow pipe into the water tank.

WARNING⚠

Be sure that the coolant temperature is low enough so that hot coolant does not spout out when you loosen the pressure cap.

- Run the engine to bring the coolant temperature to approximately 90°C {194°F}.
- If air bubbles **A** continuously rise in the water tank, it is an indication that air or exhaust gas has gotten into the coolant.
- If it is air, it is possible that the cylinder head bolts, the water pump mounting bolts or the hose connections are loose, or that the hose is damaged.
- If it is exhaust gas, it is possible that the cylinder head gaskets are damaged, or that the cylinder head is cracked.

Location	Parts to be tightened	Tightening torque	Remarks
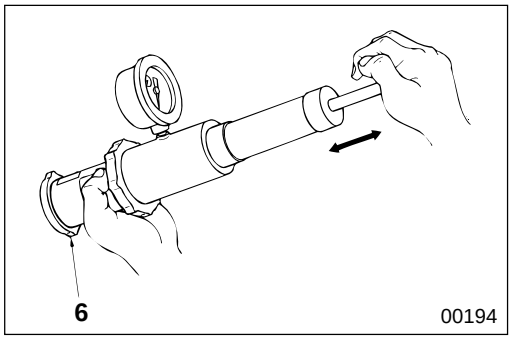
4	Water level sensor	2.9 to 3.9 {2.2 to 2.9, 0.3 to 0.4}	—

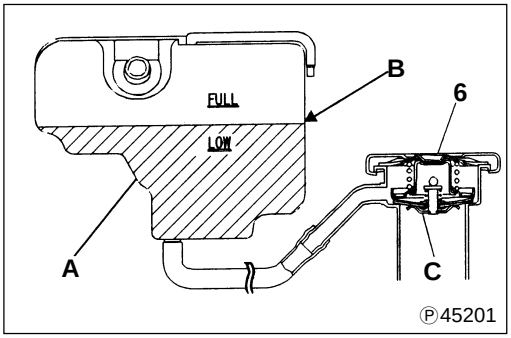
◆ Service procedure



6 **Inspection of pressure cap**

(1) Pressure valve opening pressure

If the measured value deviates from the standard value, replace pressure cap **6**.

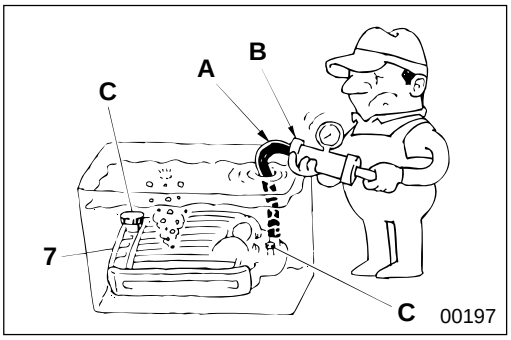


(2) Inspection of vent valve

- Take note of liquid level **B** of reservoir tank **A** before testing.
- Run the engine at a high revolution and stop engine before the overflow reaches the capacity of tank **A**.
- Leave things for a while. Check the time it takes for the coolant temperature to return to the ambient temperature, and check whether the coolant level in tank **A** is the same as before running the engine.
- If the coolant level has not returned to that before running engine, it means vent valve **C** is faulty, therefore replace pressure cap **6**.

NOTE

Do not remove pressure cap 6 before the coolant temperature decreases to the ambient temperature. If you do the coolant will not return to reservoir tank A because negative pressure in the radiator is lost.



7 Inspection of radiator

- Install radiator cap tester **B** by connecting hose **A** to the radiator inlet hole.
- Plug any other openings **C** with plugs, and immerse the radiator in a water tank.
- Apply specified air pressure of 150 kPa {21 psi, 1.5 kgf/cm^2} using cap tester **B**, and check if there is any air leakage.
- If you find air leakage, correct or replace radiator **7**.

CAUTION⚠

- **Be sure to replace automatic cooling fan coupling 5 as an assembly if it is faulty because it is a unit construction.**
- **Be sure to replace V-belts 2 as a set to maintain even tension between them.**

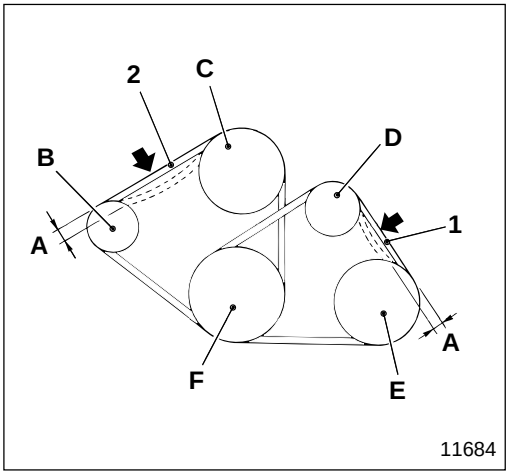
Special tools

Unit : mm {in.}

Location	Tool name and shape	Part No.	Application
1, 2	Belt tension gauge 03612	MH062345 (Obtain Locally)	Measurement of tension of V-belt

◆ Service procedure

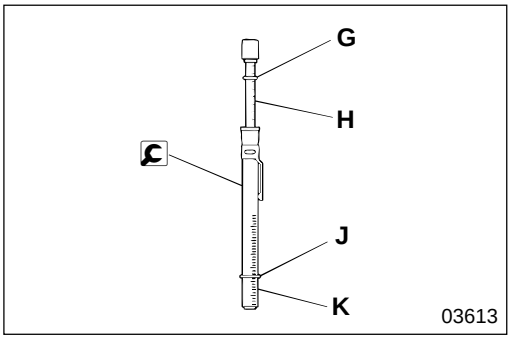


11684

1 **2** **V-belt**

[Inspection]
Measure the extent of flex **A** when the center of V-belts **1**, **2** as illustrated is depressed with a force of approximately 98 N {72 lbf, 10 kgf}.

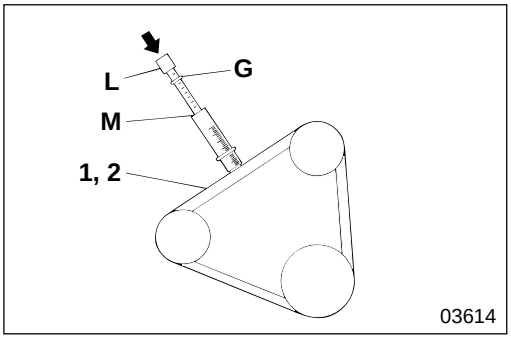
B : Alternator pulley
C : Water pump pulley
D : Tension pulley
E : Cooler compressor pulley
F : Crankshaft pulley



03613

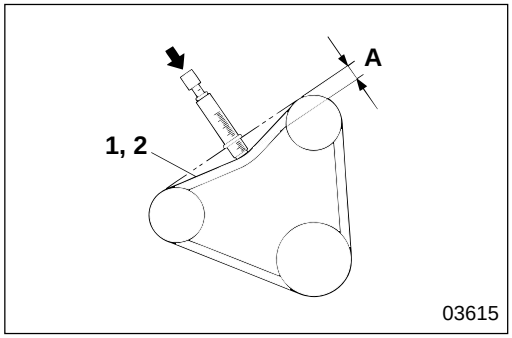
● **Use of special tool belt tension gauge**

- Set upper O-ring **G** of 🔧 belt tension gauge to 98 N {72 lbf, 10 kgf} (push load) on graduation **H**.
- Set lower O-ring **J** of 🔧 belt tension gauge to graduation **K** (maximum flex of belt).

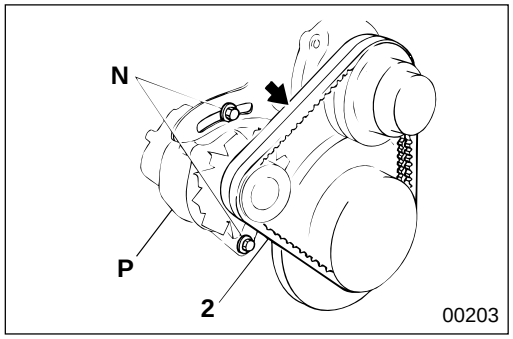


03614

- Place 🔧 belt tension gauge at the center of V-belts **1**, **2** perpendicularly as illustrated and push top **L** all the way down until upper O-ring **G** hits upper edge **M**.



- Measure the extent of flex **A** of V-belts **1**, **2** at this point, and if the measured value deviates from the standard value, adjust as follows.



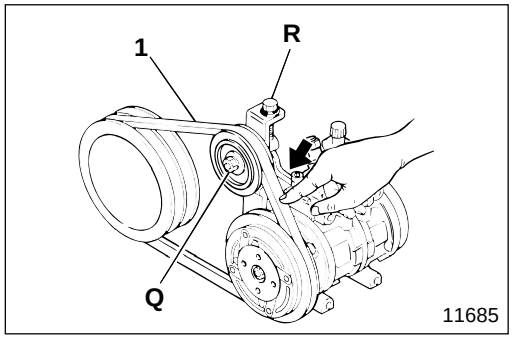
[Adjustment]

(1) Adjustment of V-belt tension for fan

- Loosen alternator mounting bolts **N** (two places), and adjust the tension of V-belts **2** by moving alternator **P** left or right.
- After adjustment, tighten the bolts and nuts securely.

CAUTION⚠

- **Bear in mind that excessive tension of V-belts 2 might damage the belts and bearings that engage with the V-belts.**
- **Be sure to replace V-belts 2 as a set to maintain even tension between them.**
- **Be careful not to let oil stick to V-belts 2, if oil gets onto the belts, it causes slipping, resulting in overheating and insufficient battery charging.**

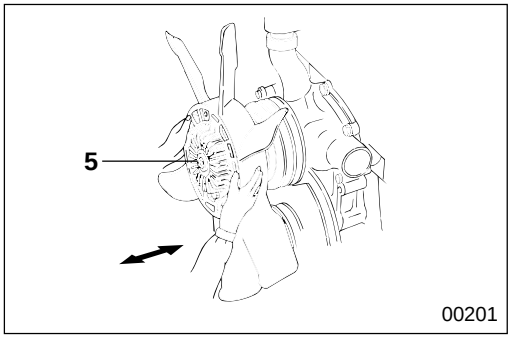


(2) Adjustment of V-belt tension for air-conditioner

- Loosen tension pulley mounting nut **Q**, and adjust the tension of V-belt **1** by adjusting bolt **R**.
- After adjustment, tighten the bolts and nuts securely.

CAUTION⚠

- **Bear in mind that excessive tension of V-belt 1 might damage the belt and bearings that engage with the V-belt.**
- **Be careful not to let oil stick to V-belt 1, if oil gets onto the belt, it causes slipping, resulting in poor performance of the air-conditioner.**

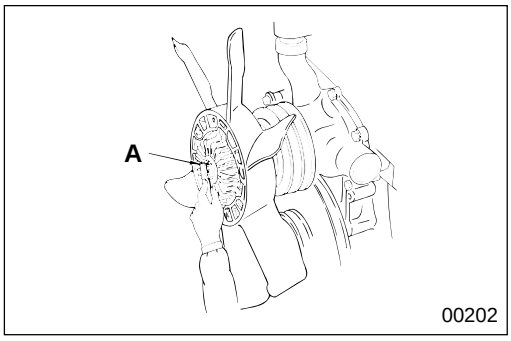


5 Automatic cooling fan coupling

[Inspection]

Carry out the following inspection of automatic cooling fan coupling **5** and if any fault is found, replace the unit.

- Check for any leakage of lubricating oil sealed in the coupling body.
- Rotate automatic cooling fan coupling **5** by hand, and check for any irregularity in rotation related to the coupling bearing or any abnormal noise.
- Check for any excessive play of automatic cooling fan coupling **5** in the axial direction when the engine is cool.



[Cleaning]

- If there are any foreign particles sticking to bimetal **A**, remove them by brushing lightly.

[Inspection]

Stir the water using stick **A** to maintain an even water temperature in the container, then carry out the following tests. If the measured value deviates from the standard value, replace thermostat **4**.

(1) Valve opening temperature

- Hold thermostat **4** with wire **E** so as not to get the thermostat too close to heat **D**.
- Heat the water gradually to raise the temperature to the valve opening temperature.
- Maintain this temperature for five minutes and make sure that valve **B** has opened.
- Make sure that valve **B** has closed when the water temperature has dropped to 65°C {149°F}.

C : Water temperature gauge

(2) Extent of valve lift

Measure valve lift **F**, while maintaining the water temperature a little higher than the valve opening temperature, with valve **B** fully open for five minutes.

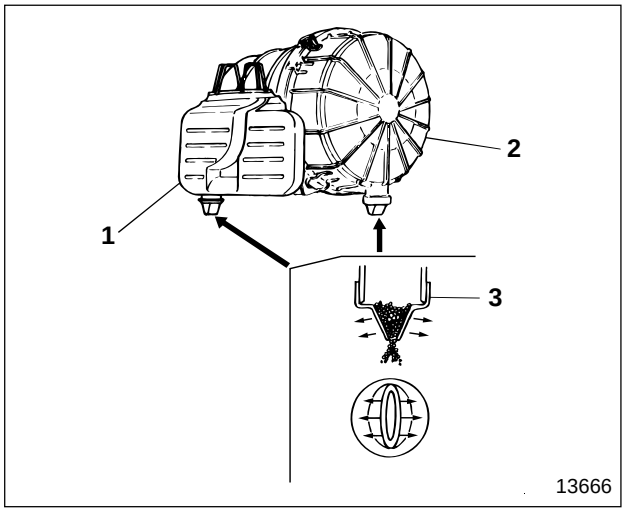
SPECIFICATIONS

Items		Specifications
Air cleaner element		Cyclone paper filter type
Turbocharger	Model	TD07
	Manufacturer	MITSUBISHI HEAVY INDUSTRIES
Intercooler type		Air-cooled, tube and corrugated fin type

STRUCTURE AND OPERATION

Air Cleaner



1 Air lower duct
2 Air cleaner assembly
3 Evacuator valve

- Air cleaner assembly **2** uses a single element.
- Evacuator valves **3** are fitted with air lower duct **1** and air cleaner assembly **2**.
- Evacuator valves **3** automatically vent dust and dirt by the repercussive force of the rubber of the valve that overcomes the inner negative pressure when the engine revolution falls below the specified revolution.

2 Compressor wheel
3 Piston ring
4 Thrust sleeve

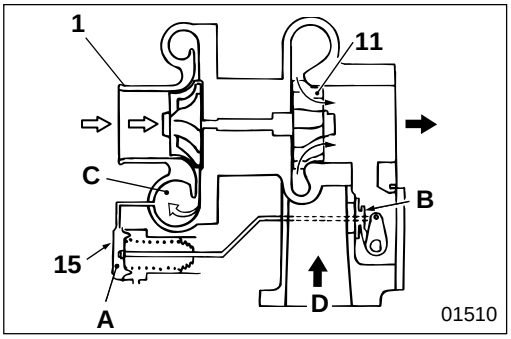
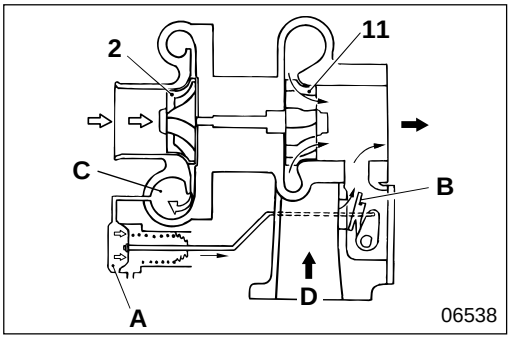
15 Actuator

Waste gate mechanism

- The waste gate mechanism relieves the boost pressure of excess exhaust gas using actuator **15**. This controls the boost pressure appropriately and prevents the turbocharger from overrunning, and prevents excessive pressure in the intake manifold.
- The boost pressure is fed into chamber **A** of actuator **15** from compressor cover **1** via a rubber hose. When boost pressure **C**, acting on chamber **A**, is lower than the preset value, the actuator does not operate and waste gate valve **B** remains closed, therefore exhaust gas **D** is blown against shaft and turbine wheel **11**.

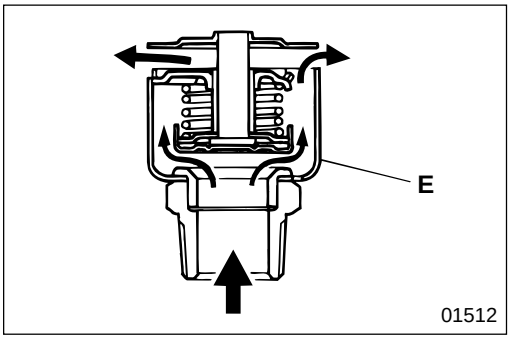




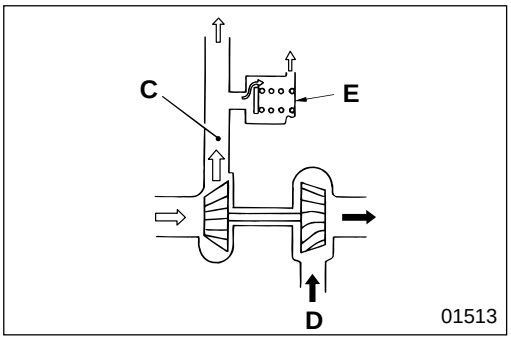
- As the boost pressure acting on chamber **A** increases to become higher than the preset value, waste gate valve **B** is opened and the exhaust gas blown against shaft and turbine wheel **11** decreases. Therefore the rotation of compressor wheel **2** decreases, causing the boost pressure to decrease.

Operation of over-boost valve

- Over-boost valve **E** operates when the boost pressure increases abnormally because of faulty operation of the waste gate mechanism.

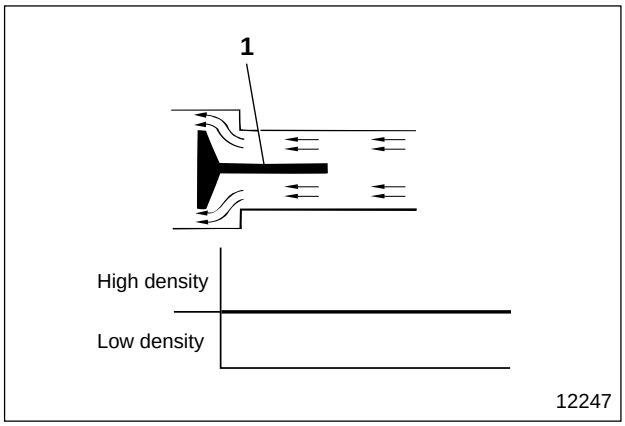


- If boost pressure **C** of over-boost valve **E** increases to become higher than the preset value, the excessive boost pressure is discharged into the atmosphere, protecting the engine from excessive boost pressure. When the valve is operating, a pipe-blowing sound is generated.

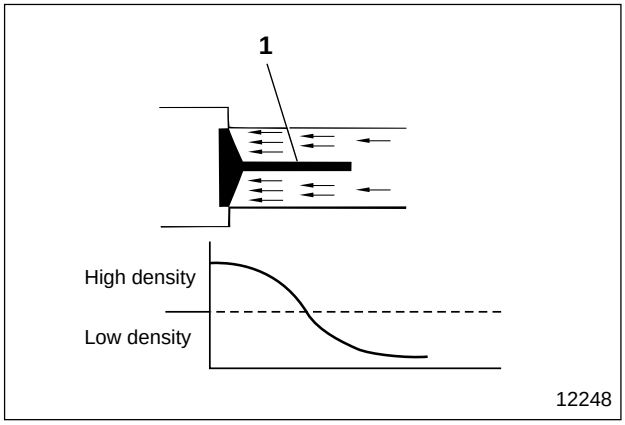


Inertia Supercharger

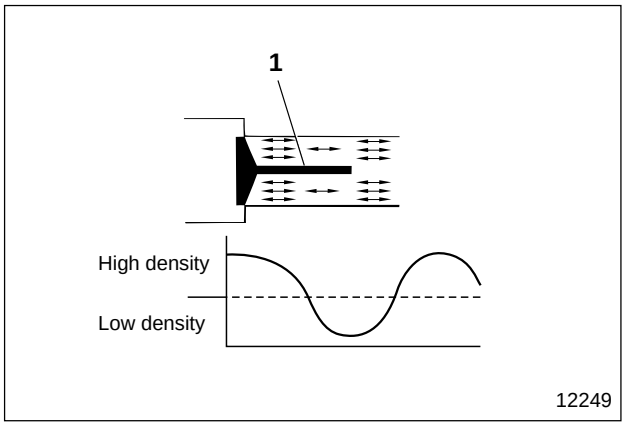
The inertia supercharger increases air intake by using the compressional wave of air generated by the air density in the intake manifold that is created by the inertia force of the air.
This supercharger improves engine performance in the low speed range where the air supply might be lower than necessary.



When inlet valve **1** is open, there is stable air flow in the intake manifold.

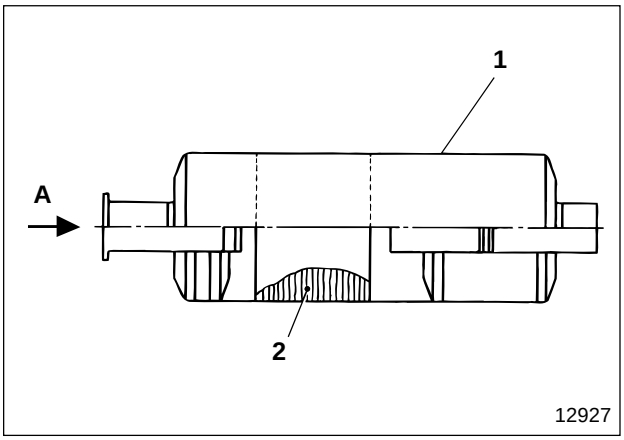


When inlet valve **1** closes and the air flow stops suddenly, the air around the inlet valve is compressed by the inertia force of the air, generating a compressional wave of air in the inlet manifold.



An intake coupler, which is split into two parts, resonates to amplify the compressional wave of air that is generated in each air conduit. When inlet valve **1** opens again, the air flows through an area where the air density is high, thus supplying a large mass of air to the combustion chamber.

Muffler



1 Muffler
2 Catalytic converter

A : Exhaust gas intake

Converter **2** is built into muffler **1** to decrease the amount of particulate matter (PM) in the exhaust gas.

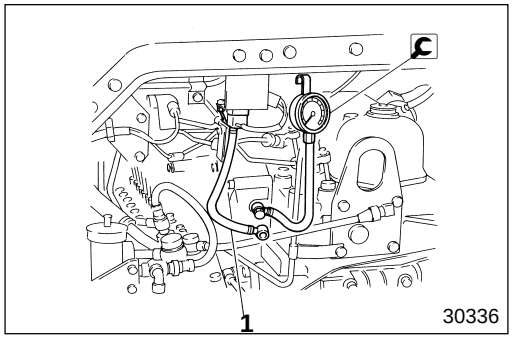
Measurement of Turbo Boost Pressure

Service standards

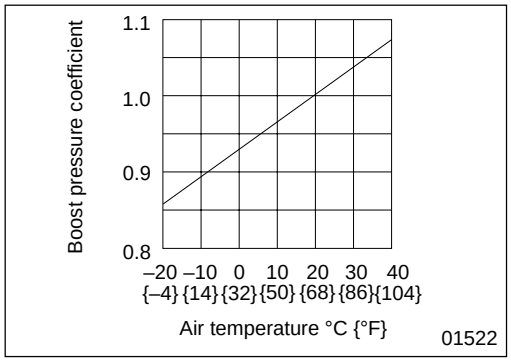
Location	Maintenance item		Standard value	Limit	Remedy
—	Boost pressure (Air temperature 20°C {68°F}, Atmospheric pressure 100 kPa {29.9 in. Hg, 760 mmHg})	6D16T2	—	38 kPa {11 in. Hg, 280 mmHg}/ 3200 rpm	Inspect and adjust
		6D16T3	—	40 kPa {11.8 in. Hg, 300 mm Hg} / 3275rpm	Inspect and adjust

Special tools

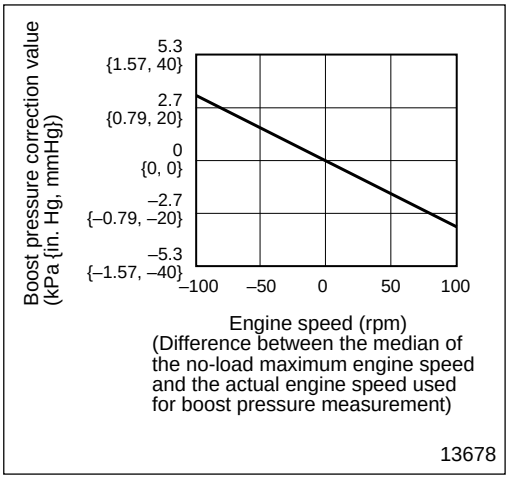
Location	Tool name and shape	Part No.	Application
—	Boost pressure gauge  01524	MH061366	Measurement of turbo boost pressure



- Before measuring the turbo boost pressure, clean or replace the air cleaner element.
- Remove boost compensator hose **1** and attach boost pressure gauge.
- After warming up the engine, measure the boost pressure at the no-load maximum engine speed. Also measure the engine speed and the air temperature.



- Correct the boost pressure at standard conditions. (Since the boost pressure varies depending on the air temperature and engine speed.)
  [Correction for air temperature]
  Identify boost pressure coefficient depending on the air temperature from the graph.



[Correction for engine speed]
Subtract the engine speed actually used for measuring the boost pressure from the median of the no-load maximum engine speed. Identify the boost pressure correction value (**Pa**) according to the graph.

Median value : 3200 rpm < 6D16T2 >
3275 rpm < 6D16T3 >

[Calculation of corrected boost pressure]
Given the measured boost pressure to be **P**, corrected boost pressure **Pb** can be calculated from the following equation:

Pb = ktP + Pa

- **Pb** : Corrected boost pressure
- **P** : Measured boost pressure
- **kt** : Boost pressure correcting coefficient depending on air temperature
- **Pa** : Boost pressure correction value

If **Pb** is lower than the limit, the turbocharger must be inspected and adjusted.

◆ Service procedure

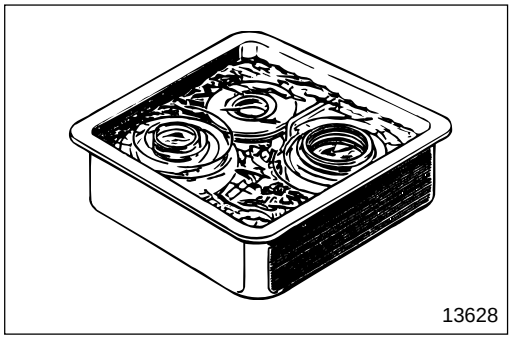
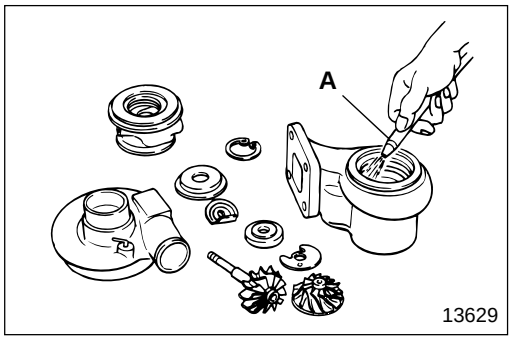
● Work before disassembly

Put alignment marks **A** on coupling assembly **3**, turbine housing **4**, compressor cover **6** and bearing housing **24**.

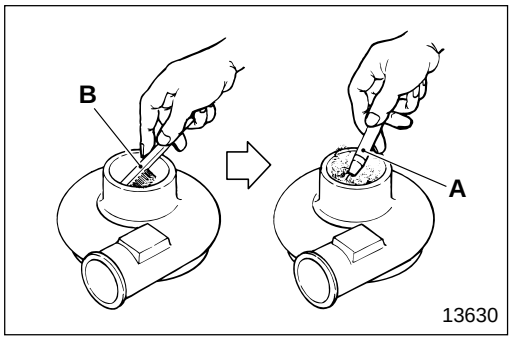


● Cleaning after disassembly

- Visually inspect related parts before cleaning to check if there are any burns or scratches as these would not be seen after cleaning. If any fault is found, replace the faulty parts.
- Immerse the disassembled parts in a nonflammable solvent (DAIDO KAGAKU KOGYO DAICLEANER T-30).



- Take the parts out and blow compressed air **A** on them.



- Scrape foreign particles off.
  B : Plastic scraper or bristle-headed brush
- Immerse the parts again in the solvent.
- Blow compressed air **A** on them.

CAUTION

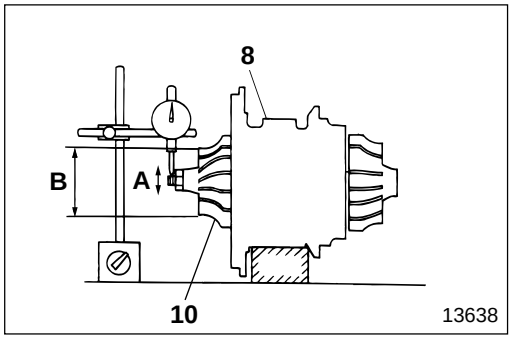
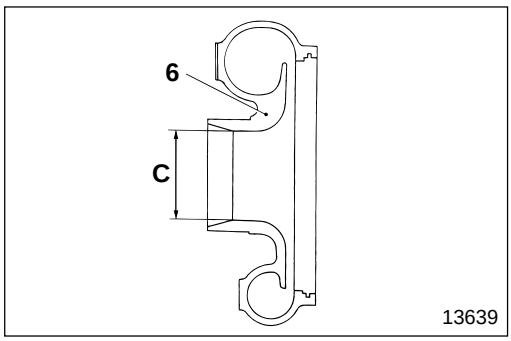
- **When removing compressor cover 6, tap all around the circumference lightly so as not to damage the compressor cover.**
- **Avoid hitting compressor wheel 10 near compressor cover 6, since the blade of the compressor wheel can be easily bent.**



6 **8** **Inspection of clearance between wheel and bearing housing assembly and compressor cover**

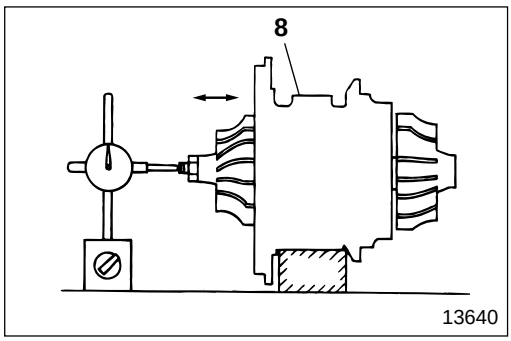
- Measure deflection **A**.
- Measure outer diameter **B** of compressor wheel **10**.



- Measure inner diameter **C** of compressor cover **6**.
- Calculate the clearance between wheel and bearing housing assembly **8** and compressor cover **6** using the following equation.

$$\text{Clearance} = \frac{\mathbf{C} - \mathbf{B} - \mathbf{A}}{2}$$

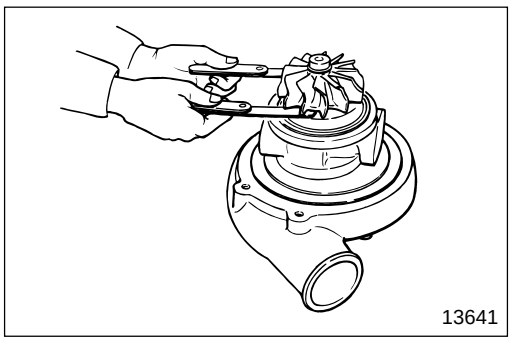
- If the calculated clearance deviates from the standard value, disassemble and determine the cause.



8 **Inspection of wheel and bearing housing assembly**

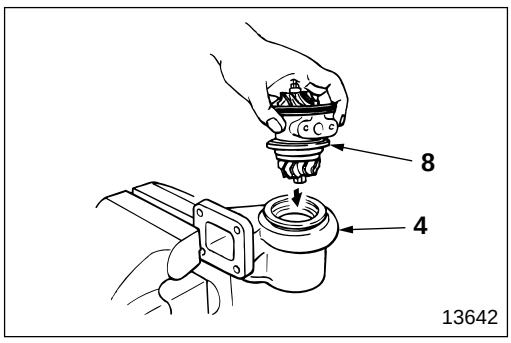
(1) Play in the shaft direction

If the measured value deviates from the standard value, disassemble and determine the cause.



(2) Clearance between turbine backplate and shaft and turbine wheel rear side.

- Measure using the tip of two feeler gauge blades.
- If the measured value deviates from the standard value, disassemble and determine the cause.



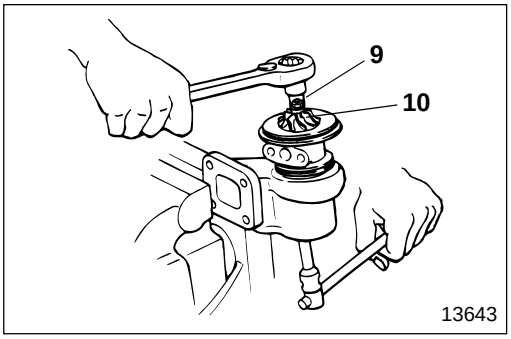
10 **Compressor wheel**

[Removal]

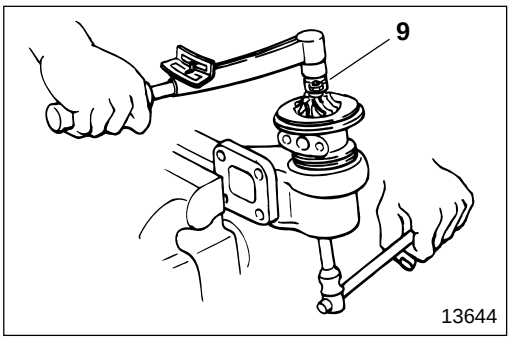
- Install wheel and bearing housing assembly **8** in turbine housing **4**.

CAUTION

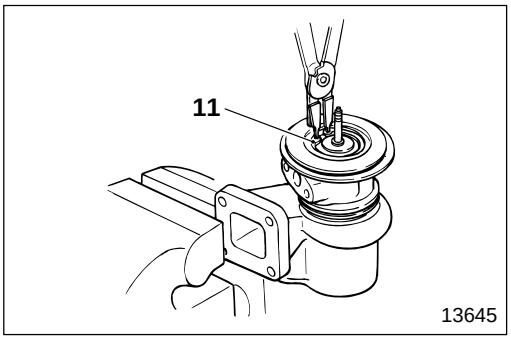
Avoid hitting shaft and turbine wheel 21 near turbine housing 4, since the blade of the shaft and turbine wheel can be easily bent.



- Remove lock nut **9** while holding the boss of shaft and turbine wheel **21**.



[Installation]
Tighten lock nut **9** at specified torque while holding the boss of shaft and turbine wheel **21**.



11 **Snap ring**

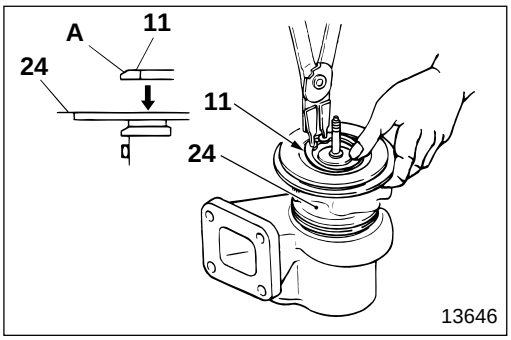
WARNING

When removing snap ring 11, hold it with your hand to prevent it from springing out.

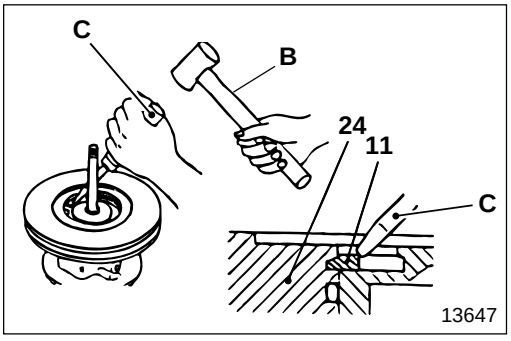


[Installation]

- Install snap ring **11** onto bearing housing **24** in the direction as illustrated.
  A : Tapered surface

WARNING

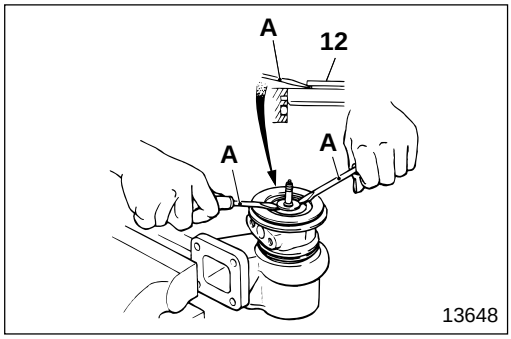
When installing snap ring 11, hold it with your hand to prevent it from springing out.



- Install so that snap ring **11** fits into the groove of bearing housing **24** fully.
  B : Mallet
  C : Screwdriver

CAUTION

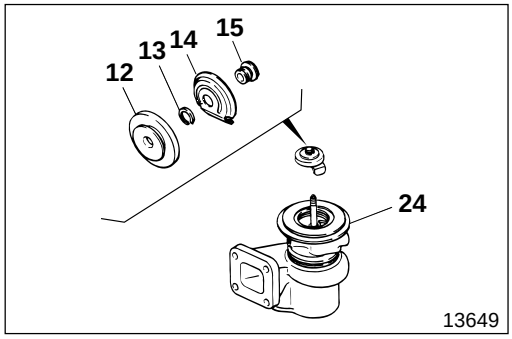
Make sure you do not hit bearing housing 24 with screwdriver C.



12 **Insert**

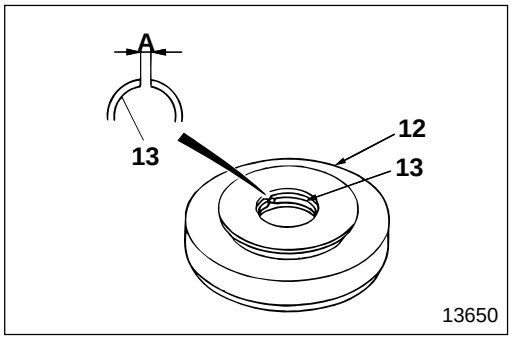
[Removal]

A : Screwdriver



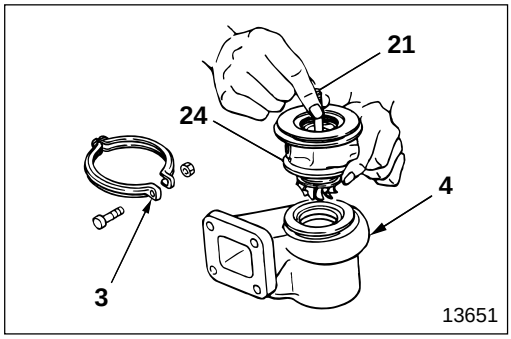
[Installation]

Install oil deflector **14** onto bearing housing **24** in the direction as illustrated.



13 **Inspection of clearance of piston ring split**

- Install new piston ring **13** in insert **12**.
- Measure clearance **A** of the split of piston ring **13**.
- If the measured value deviates from the standard value, replace inserter **12**.

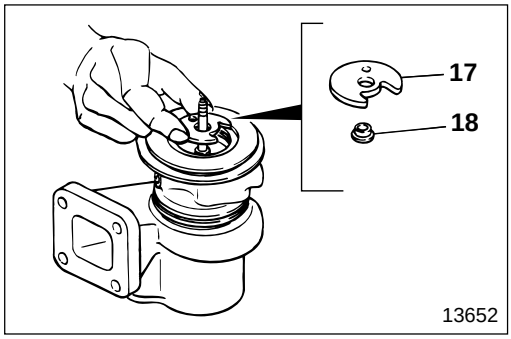


17 **18** **Installation of thrust bearing and thrust ring**

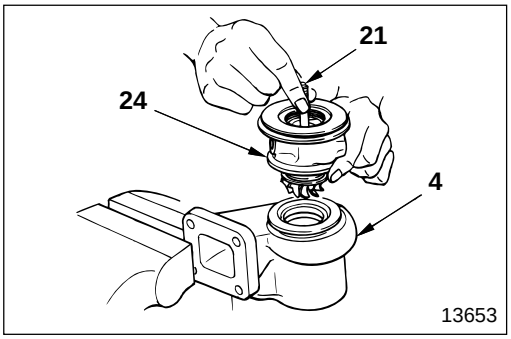
- Install parts **19** to **23** into bearing housing **24**.
- Hold shaft and turbine wheel **21** and bearing housing **24** with your hand and install them in turbine housing **4**.
- Fix temporarily using coupling assembly **3**.

CAUTION

- **Avoid hitting shaft and turbine wheel 21 near turbine housing 4, since the blade of the shaft and turbine wheel can be easily bent.**
- **Do not drop shaft and turbine housing 21.**



- Install thrust bearing **17** and thrust ring **18** so that the thrust bearing faces the direction as illustrated.

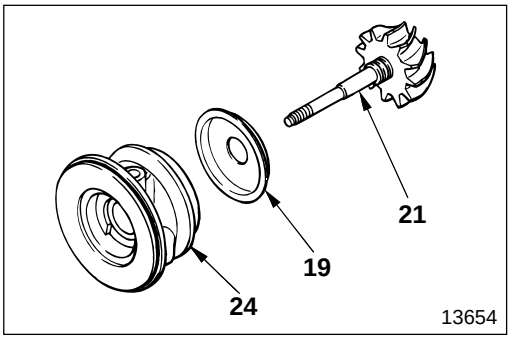


19 Removal of turbine backplate

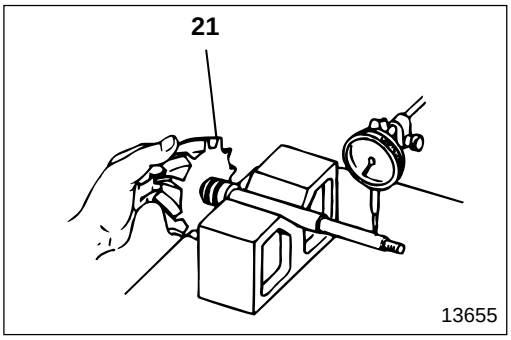
- Hold shaft and turbine wheel **21** and bearing housing **24** with your hand and remove them from turbine housing **4**.

CAUTION

- **Avoid hitting shaft and turbine wheel 21 near turbine housing 4, since the blade of the shaft and turbine wheel can be easily bent.**
- **Do not drop shaft and turbine housing 21.**



- Remove turbine backplate **19**.

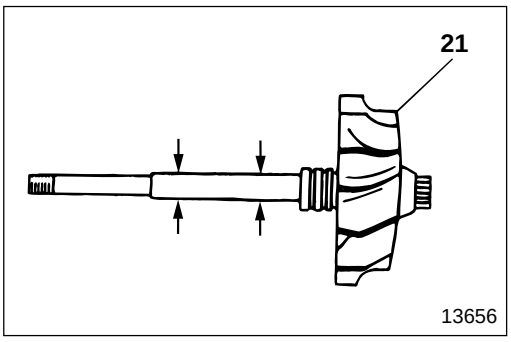


21 Shaft and turbine wheel

[Inspection]

(1) Bend of shaft

- Measure the bend at the position as illustrated.
- If the measured value is higher than the limit, replace shaft and turbine wheel **21**.



(2) Outer diameter of journal

If the measured value is lower than the limit, replace shaft and turbine wheel **21**.

(3) Smoothness of journal

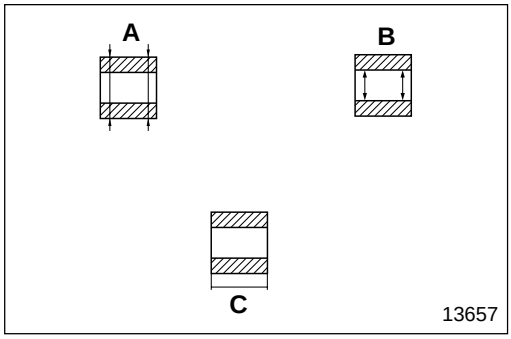
If the journal is rough, correct it.

[Correction]

- Mount shaft and turbine wheel **21** between two centers on a lathe.
- Polish the journal softly with emery paper (400 grit) and engine oil.

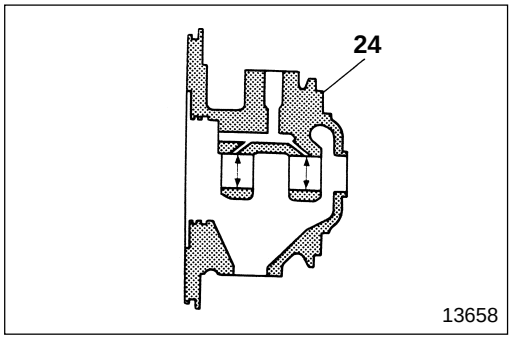
CAUTION

Be sure to measure the outer diameter of the journal after polishing it.



22 **Inspection of bearing**

- Measure at three points as illustrated.
  A : Outer diameter
  B : Inner diameter
  C : Length
- If the measured value of the inner diameter is higher than the limit, or if the outer diameter or the length is lower than the limit, replace bearing **22**.



24 **Inspection of bearing housing**

- Measure the inner diameter of bearing **22** installation area.
- If the measured value is higher than the limit, replace bearing housing **24**.

◆ Service procedure

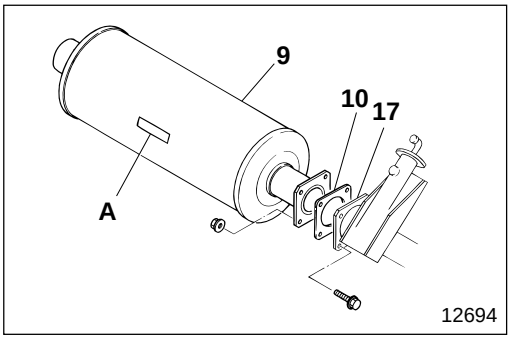
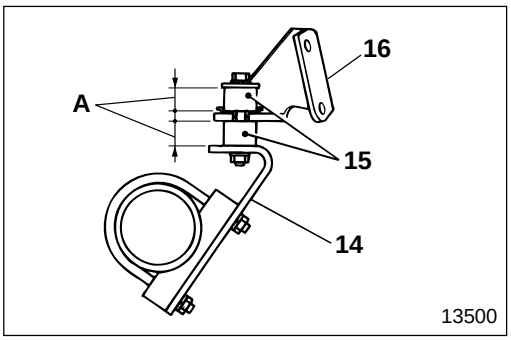
2 **Installation of clamp assembly**

- Tighten nut **1** temporally to let clamp **3** move slightly.
- Tighten nut **1** until it makes contact with area **A** of clamp **3**.
- After tightening area **A**, tighten area **B** using nut **1**.
- Tighten until dimension **C** of rubber cushion **5** is as follows:
  C : Before tightening 25 mm {0.98 in.}
  After tightening 23 mm {0.91 in.}



9 **Installation of muffler**

Install muffler **9** to front pipe assembly **17** in the direction as illustrated.
A : Part No. marked position



12 **Installation of clamp assembly**

Tighten until dimension **A** of rubber cushion **15** is as follows:
A : Before tightening 25 mm {0.98 in.}
After tightening 23 mm {0.91 in.}

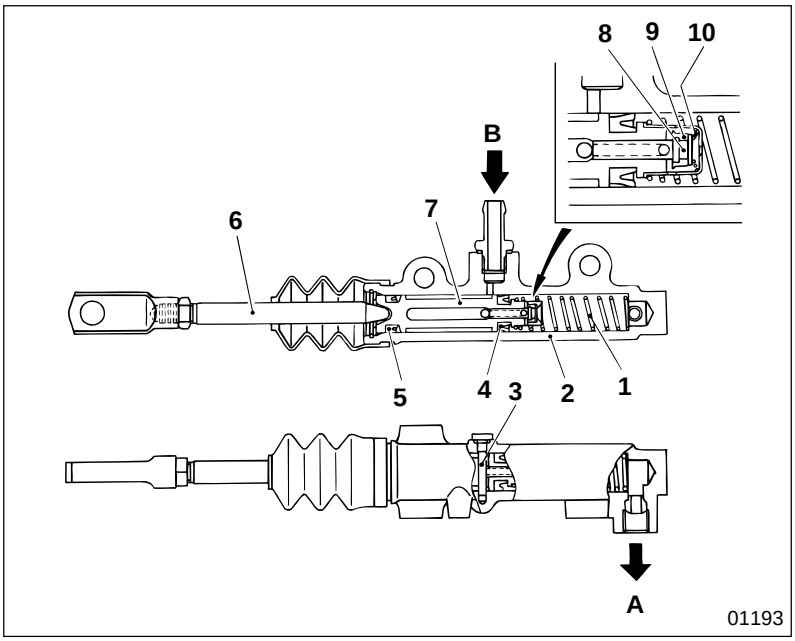
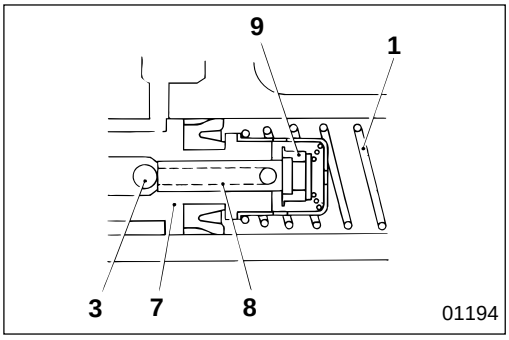
Clutch Master Cylinder



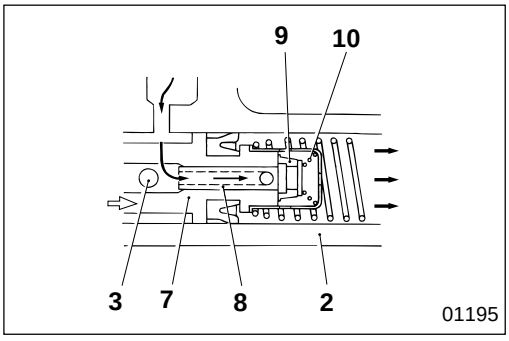
1 Return spring
2 Cylinder
3 Supply valve stopper
4 Primary cup
5 Secondary cup
6 Push rod
7 Piston
8 Supply valve rod
9 Supply valve
10 Supply valve spring

A : To clutch power cylinder
B : From fluid tank



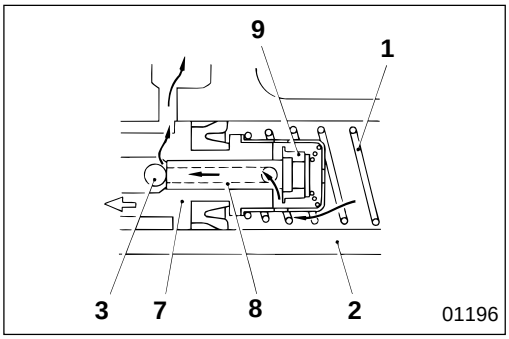
Before clutch pedal is depressed

- As piston **7** is pressed in the direction of push rod **6** by return spring **1**, supply valve rod **8** rests at supply valve stopper **3**, and supply valve **9** remains open.
- This opens the passage between the fluid tank and the clutch.



When clutch pedal is depressed

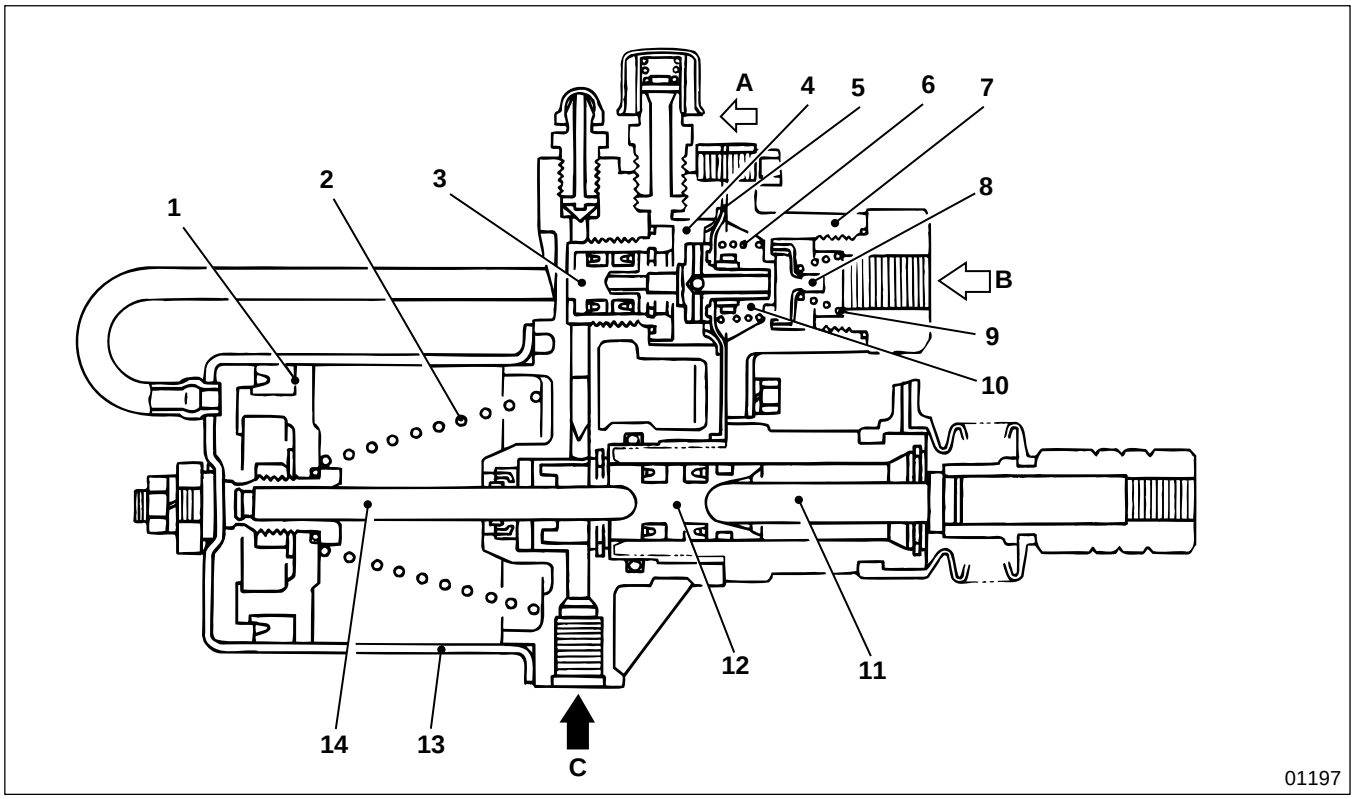
- As push rod **6** pushes piston **7**, supply valve rod **8** separates from supply valve stopper **3**. At the same time, supply valve spring **10** closes supply valve **9**.
- As piston **7** is pressed further, hydraulic pressure is generated inside cylinder **2** to actuate the clutch power cylinder.
- Fluid is supplied in proportion to the amount of movement of piston **7**.



When clutch pedal is released

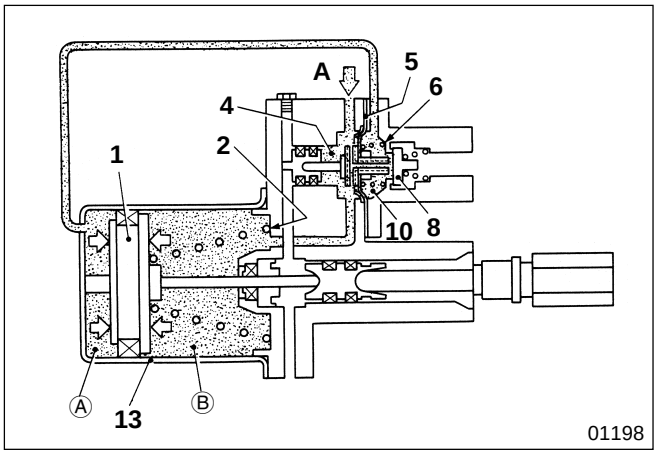
- The combined repercussive forces of the hydraulic pressure inside cylinder **2** and return spring **1** push piston **7** back, causing supply valve rod **8** to hit supply valve stopper **3**, opening supply valve **9**.
- Fluid from the clutch power cylinder returns to the fluid tank, and hydraulic pressure ceases to exist.

Clutch Booster < C7M38 (M8S2×5) >



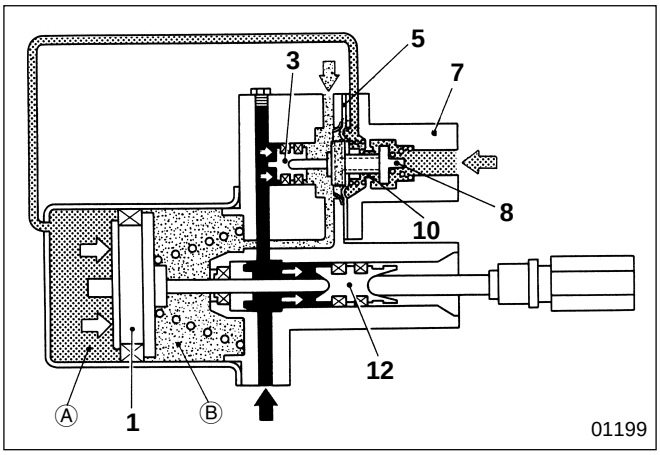
1 Power piston
2 Spring
3 Relay valve piston
4 Air chamber
5 Diaphragm
6 Spring
7 Valve body
8 Poppet valve
9 Spring
10 Control chamber
11 Rod
12 Hydraulic piston
13 Cylinder shell
14 Push rod

A : Atmospheric pressure
B : Air pressure from air tank
C : Hydraulic pressure from clutch master cylinder



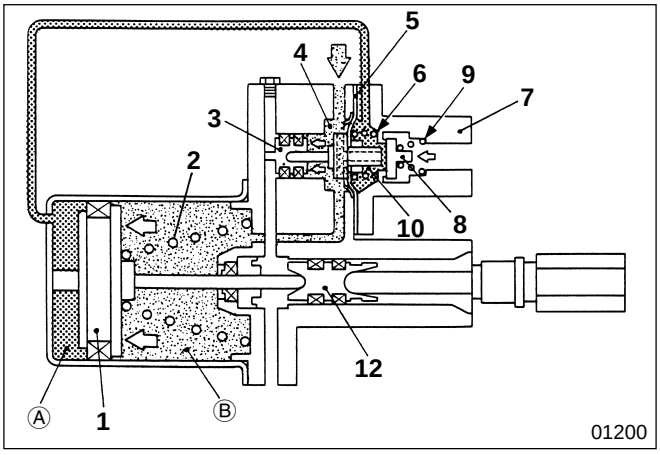
When clutch booster is not operated

- Both air chamber **4** and control chamber **10** are under atmospheric pressure **A**.
- Spring **6** pushes diaphragm **5** to the left, opening a clearance between the diaphragm and poppet valve **8**.
- This clearance connects control chamber **10** to chamber Ⓐ of cylinder shell **13**, so chamber Ⓐ is under atmospheric pressure.
- Since chamber Ⓑ of cylinder shell **13** is connected to air chamber **4**, chamber Ⓑ is under atmospheric pressure. Thus, there is no pressure difference between chambers Ⓐ and Ⓑ.
- Therefore, power piston **1** remains pushed to the left by spring **2**.



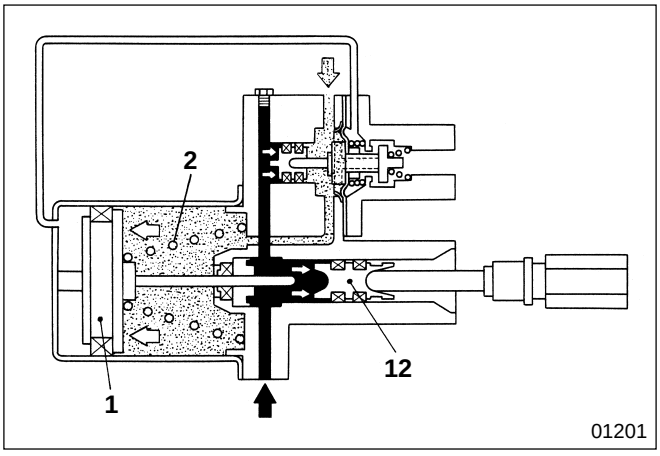
When clutch pedal is depressed

- Hydraulic pressure **C** acts on hydraulic piston **12** and relay valve piston **3**.
- Relay valve piston **3** pushes diaphragm **5** to the right and the diaphragm sticks to poppet valve **8**, closing the clearance.
- This blocks the atmospheric pressure passage between control chamber **10** and chamber Ⓐ.
- Diaphragm **5** pushes poppet valve **8** further, opening a clearance between the poppet valve and valve body **7**.
- Air pressure **B** flows into chamber Ⓐ through this clearance, creating a pressure difference between chambers Ⓐ and Ⓑ.
- This pressure difference acts on power piston **1** to push it to the right where it combines with the hydraulic pressure acting on hydraulic piston **12**, cutting off the clutch at low depression force.



When clutch pedal is released

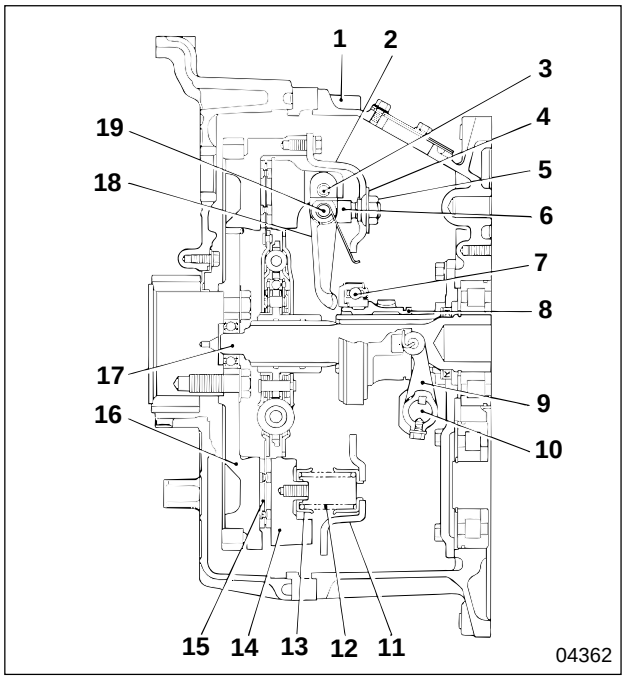
- The hydraulic pressure acting on hydraulic piston **12** and relay valve piston **3** ceases, freeing the pistons.
- Therefore, diaphragm **5** and poppet valve **8**, being pushed by relay valve piston **3**, are returned to the left by the repercussive force of springs **6**, **9**.
- Poppet valve **8** sticks to valve body **7** to block the air pressure passage to chamber Ⓐ, opening a clearance with diaphragm **5** instead.
- This clearance connects air chamber **4** to control chambers **10** and Ⓐ, and they are all under atmospheric pressure. Since the pressure difference between chambers Ⓐ and Ⓑ is lost, power piston **1** is returned to the left by the repercussive force of spring **2**.



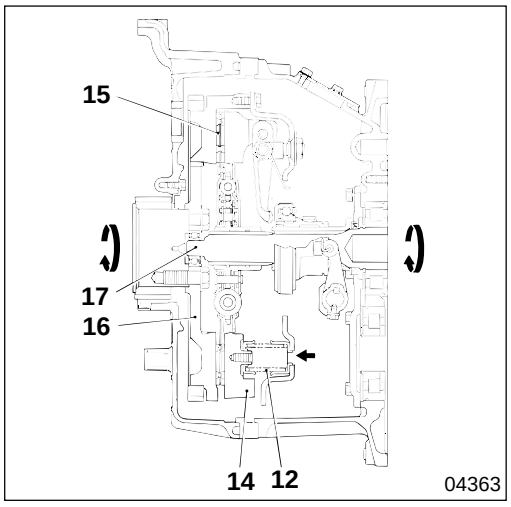
When air system is faulty

- If the air pressure fed by the air tank is lost, the air pressure in chamber Ⓐ is lost, too.
- As a result, power piston **1** is returned to the left by spring **2**.
- Therefore, the clutch is cut off solely by the hydraulic pressure applied to hydraulic piston **12**.

Clutch

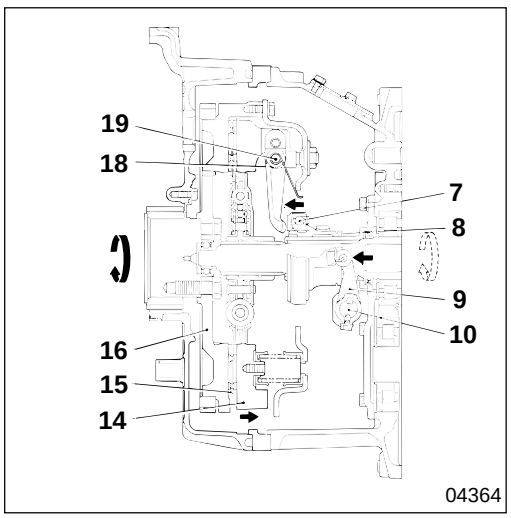


1 Clutch housing
2 Clutch cover
3 Release lever pin
4 Lock plate
5 Support nut
6 Support lever
7 Release bearing
8 Clutch shifter
9 Release fork
10 Release fork shaft
11 Pressure spring cap
12 Pressure spring
13 Pressure spring cap
14 Pressure plate
15 Clutch disc
16 Flywheel
17 Drive pinion
18 Release lever
19 Support lever pin



When clutch pedal is released

- Pressure plate **14**, activated by pressure spring **12**, forces clutch disc **15** against flywheel **16**.
- Clutch disc **15** forced against flywheel **16** runs together with the flywheel and transmits power from the engine to transmission drive pinion **17**.



When clutch pedal is depressed

- Hydraulic pressure generated within the clutch master cylinder activates the clutch power cylinder < C6 (M060S6), C7 (M070S6) >, or clutch booster < C7 (M8S2×5) >. Release fork shaft **10** actuates release fork **9** and pushes release bearing **7** forward together with clutch shifter **8**, pushing release lever **18**.
- Release lever **18**, with support lever pin **19** acting as the fulcrum, retracts pressure plate **14**, which opens a clearance between clutch disc **15** and flywheel **16**, cutting off power transmission from the engine.

Clutch Fluid (Brake Fluid) Replacement and Air Bleeding < Clutch Power Cylinder >

Tightening torque

Unit : N·m {ft.lbs, kgf·m}

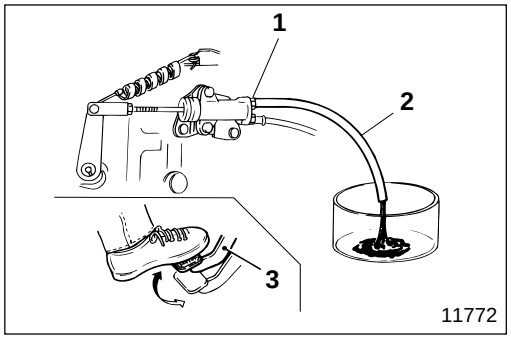
Location	Parts to be tightened	Tightening torque	Remarks
1	Air bleeder	25 to 34 {18 to 25, 2.5 to 3.5}	—

Fluid

Location	Points of application	Kinds	Quantity
4	Fluid tank	Brake fluid (SAE J1703f or FMVSS No.116 DOT3)	As required

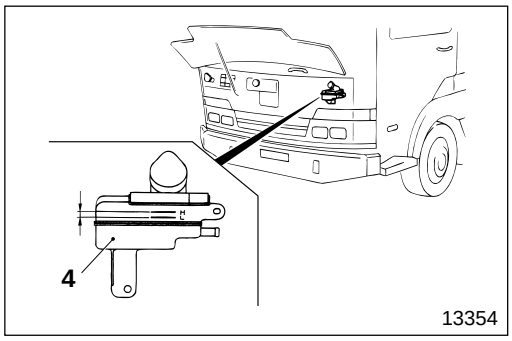
CAUTION

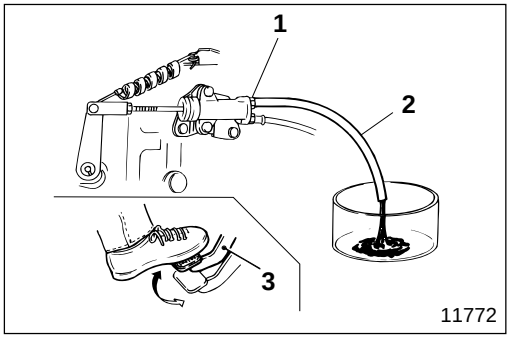
- **Be careful not to splash brake fluid on related parts as this could damage the paintwork.**
- **Be sure to wipe off brake fluid immediately if you splash it on the paintwork.**
- **You must use new brake fluid (SAE J1703f or FMVSS No. 116 DOT3). Do not add different quality fluid or mineral oil (gas oil, engine oil, gear oil, automatic transmission fluid, etc.) to the clutch system, because this will cause the rubber parts of the clutch system to swell, resulting in faulty clutch operation.**
- **Do not allow foreign particles or water to become mixed into the brake fluid when refilling, because this will cause faulty clutch operation.**
- **If you use a mug for adding brake fluid, keep it solely for that purpose to prevent contamination from different quality fluids or mineral oils.**

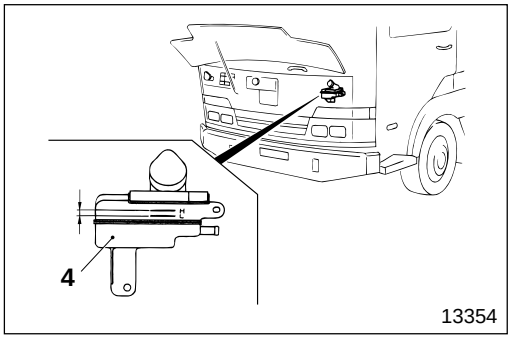


(1) Replacement of brake fluid

- Attach vinyl pipe **2** to air bleeder **1** of the clutch power cylinder.
- Loosen air bleeder **1** and depress clutch pedal **3** several times to drain brake fluid completely.
- Supply new brake fluid to the "**H**" level of fluid tank **4**. Depress clutch pedal **3** repeatedly until the old brake fluid discharged from vinyl pipe **2** is replaced by the new brake fluid.







(2) Air bleeding of clutch system

NOTE

Carry out this operation maintaining the brake fluid level in fluid tank 4 between "H" and "L".

- Attach vinyl pipe **2** to air bleeder **1** of the clutch power cylinder as in the replacement procedure.
- Fill fluid tank **4** with brake fluid, and loosen air bleeder **1** of the clutch power cylinder, then depress clutch pedal **3** continuously.
- Keep depressing clutch pedal **3**, and tighten air bleeder **1** when air is bled completely.
- Depress clutch pedal **3** several times again, then keep it depressed at its fullest extent.
- With clutch pedal **3** depressed, loosen air bleeder **1** to drain brake fluid containing air. Release the pedal after tightening the air bleeder.
- Repeat this operation until air is no longer present in the fluid being drained.
- When this operation is completed, tighten air bleeder **1** at specified torque.
- Check that brake fluid is at the "**H**" level of fluid tank **4**, and supply new brake fluid if necessary.
- Check for brake fluid leakage from each of the parts with clutch pedal **3** depressed.

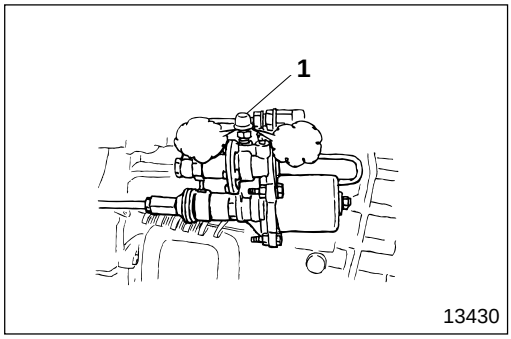
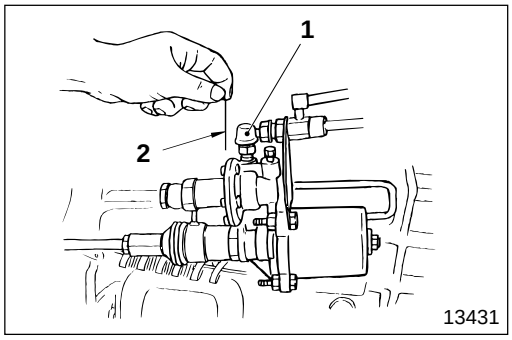
- Repeat this operation until air is no longer present in the fluid being drained.
- When this operation is completed, tighten air bleeder **1** at specified torque.
- Check that brake fluid is at the "**H**" level of fluid tank **4**, and supply new brake fluid if necessary.
- Check for brake fluid leakage from each of the parts with clutch pedal **3** depressed.

Inspection of Function < Clutch Booster >



- Make sure that the depression force required to depress the clutch pedal when the air pressure is 0 kPa {0 psi, 0 kgf/cm^2} is notably different from that when the air pressure is 590 to 785 kPa {85 to psi, 6 to 8 kgf/cm^2}.
- Make sure that air is instantly bled from exhaust cover **1** when you release the clutch pedal.



- Apply air pressure of 590 to 785 kPa {85 to 115 psi, 6 to 8 kgf/cm^2} and hang thread **2** in front of exhaust cover **1**. Make sure that the thread is not blown upward when depressing and releasing the clutch pedal.
  If the thread is blown upward, it indicates that air is leaking from the poppet valve.

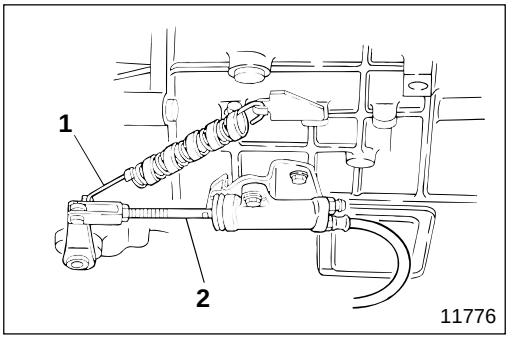
Clutch Pedal Free Play < Clutch Power Cylinder >

Service standards

Unit : mm {in.}

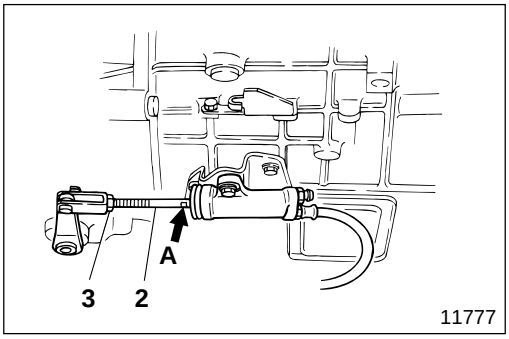
Location	Maintenance item	Standard value	Limit	Remedy
2	Push rod stroke	3.8 {0.15}	—	Adjust or replace
4	Clutch pedal free play	32 to 44 {1.25 to 1.73}	—	Adjust or replace

Inspect and adjust the free play of the clutch pedal, by noting the stroke of the clutch power cylinder push rod, after the clutch pedal has been correctly adjusted.



[Inspection]

- Bleed air from the clutch system. P21-9
- Adjust the clutch pedal. P21-18
- Remove return spring **1** and measure the free travel of push rod **2** by moving it with your hand. If the measured value deviates from the standard value, adjust as follows:

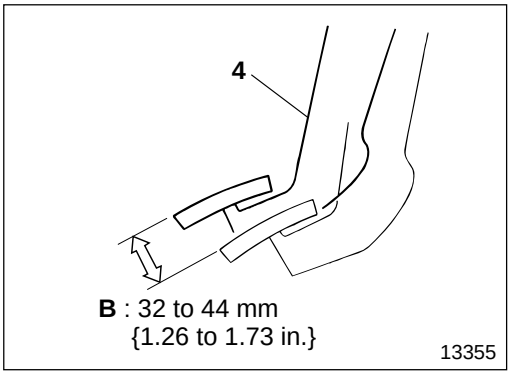


[Adjustment]

- Loosen nut **3** and turn head **A** of push rod **2** to extend the push rod until it stops.
- Then, slacken off head **A** of push rod **2** by the following value and retighten nut **3**.

  Amount of slackening off: Approximately three turns

- If push rod **2** does not return by the above amount, replace the clutch disc because it is worn beyond the limit.



[Confirmation]

Push clutch pedal **4** with your hand until you feel a resistance and measure free play **B**.

If the measured value deviates from the standard value, readjust or replace the clutch disc.

ON-VEHICLE INSPECTION AND ADJUSTMENT

Clutch Pedal Free Play < Clutch Booster >

Service standards

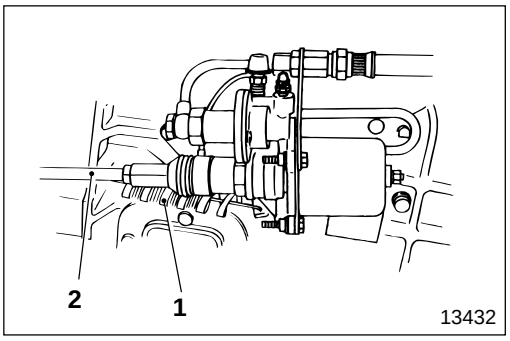
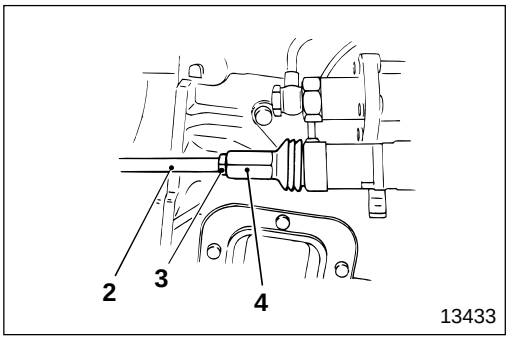
Location	Maintenance item	Standard value	Limit	Remedy
2	Push rod stroke	3.2 {0.13}	—	Adjust or replace
5	Clutch pedal free play	35 to 47 {1.38 to 1.85}	—	Adjust or replace

Inspect and adjust the free play of the clutch pedal, by noting the stroke of the clutch booster push rod, after the clutch pedal has been correctly adjusted.



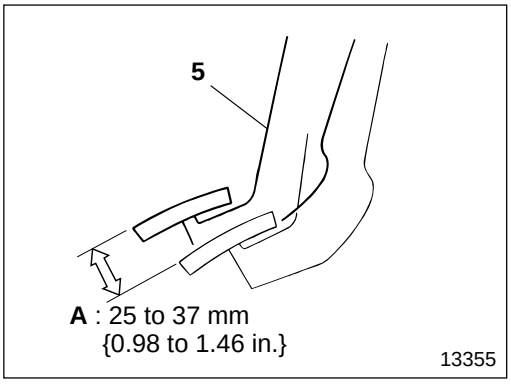
[Inspection]

- Bleed air from the clutch system. P21-11
- Adjust the clutch pedal. P21-22
- Remove return spring **1** and measure the free travel of push rod **2** by moving it with your hand. If the measured value deviates from the standard value, adjust as follows:



[Adjustment]

- Loosen nut **3** and turn head **4** of push rod **2** to extend the push rod until it stops.
- Then, slacken off head **4** of push rod **2** by the following value and retighten nut **3**.
  Amount of slackening off: Approximately two and three-fifth turns
- If push rod **2** does not return by the above amount, replace the clutch disc because it is worn beyond the limit.



[Confirmation]

Push clutch pedal **5** with your hand until you feel a resistance and measure free play **A**.
If the measured value deviates from the standard value, readjust or replace the clutch disc.

◆ Service procedure

1 **Removal and installation of fluid hose**

- When removing fluid hose **1**, first disconnect from pipe **A** on the frame side, then disconnect from clutch booster assembly **17**.
- For installation, follow the removal sequence in reverse.
- After installing fluid hose **1**, bleed the system.

CAUTION⚠

After removing fluid hose 1, fit blanking plug B into pipe A to prevent fluid from flowing out.

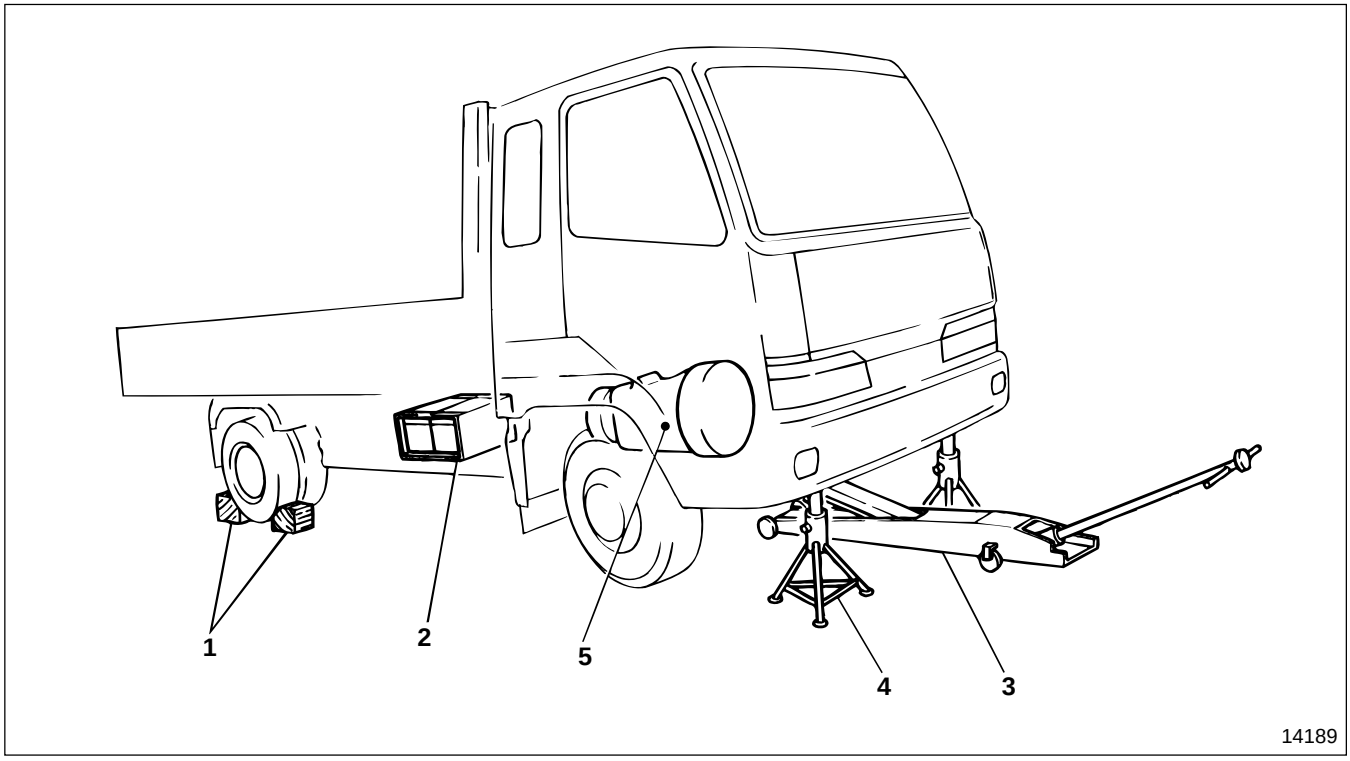
WORK BEFORE REMOVAL AND INSTALLATION OF CLUTCH BODY



● **Work sequence before removal**

1 Place wheel chocks.
2 Disconnect the negative battery cable. Gr 54
3 Jack up the front axle using a garage jack.
4 Support the front frame on rigid racks.
5 Remove the transmission. Gr 22A, B

WARNING⚠

- **Since the parking brake (center parking) will be removed, naturally it cannot be used. Therefore, you must chock the wheels securely so the vehicle does not move.**
- **Do not remove the chocks until the entire operation is completed.**
- **Supporting a vehicle on a garage jack only is extremely dangerous, so always support the frame on rigid racks.**
- **Leave the garage jack and rigid racks in place until the entire operation is completed. Never remove them during the operation.**

CAUTION⚠

Keep the transmission in neutral throughout the operation.

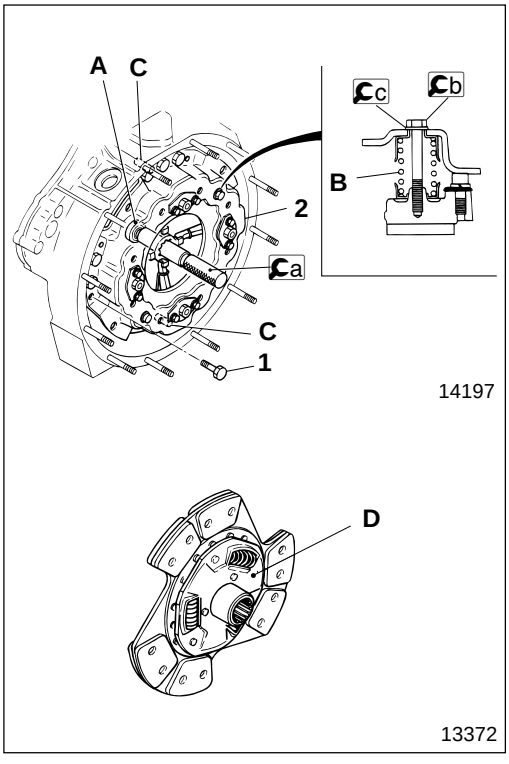
◆ Service procedure

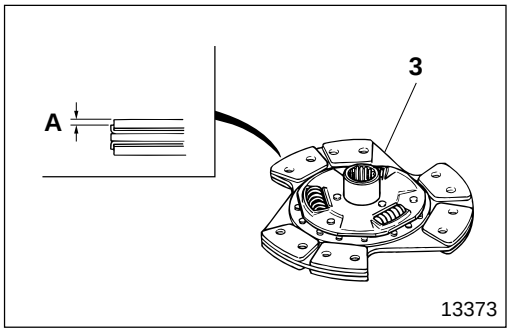


2 Removal and installation of pressure plate and lever assembly

- Insert a clutch alignment arbor in flywheel pilot bearing **A** to hold clutch disc **3**.
- Compress springs **B** using b stopper bolt and c washer, then remove bolt **1**.
- For installation, follow the removal sequence in reverse.
- Install clutch disc **3** so that part No. **D** is visible.
- Tighten bolts **1** gradually, in diagonal order, to specified torque.

CAUTION ⚠

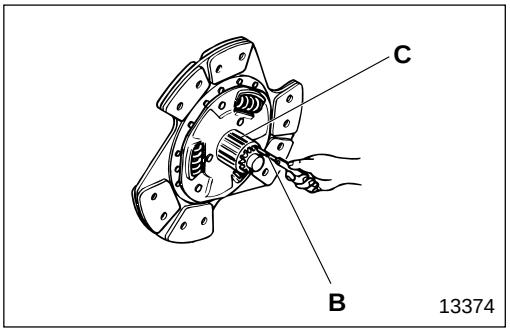
- **Beware, if you do not use b stopper bolts and c washers (four points) to remove bolt 1, the force of springs B might push out pressure plate and lever assembly 2, damaging the strap plate. It might even come apart from knock pin C and drop off.**
- **Remember to remove stopper bolts and washers after installation (four points). If the stopper bolts and washers are left on, the clutch will not engage.**



3 Clutch disc

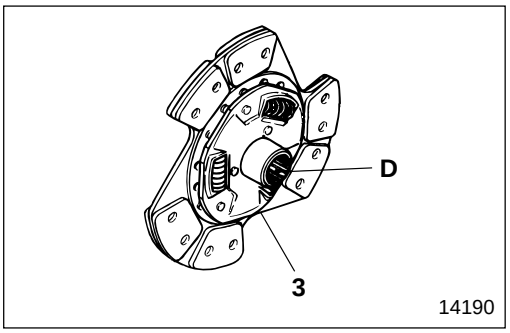
(1) Thickness of facing

Measure dimension **A** as illustrated.
If the measured value does not conform to the standard value, replace clutch disc **3**.



(2) Play in direction of revolution

- Reshape feeler gauge **B** for insertion into drive pinion spline **C**, and measure play.
- If the measured value is higher than the limit, replace clutch disc **3** or the drive pinion.
- Carry out the same measurement on new clutch disc **3**. If the measured value is higher than the limit, replace the drive pinion.



(3) Applying grease

Apply grease evenly to spline **D** and the entire tooth surface of clutch disc **3**. Apply grease to the grease groove of the spline up to its large diameter.

CAUTION

Be careful not to apply too much grease because excessive grease causes grease leakage from spline D and makes the clutch slippery.

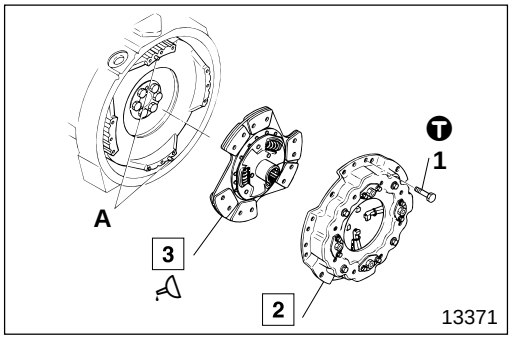
◆ Service procedure



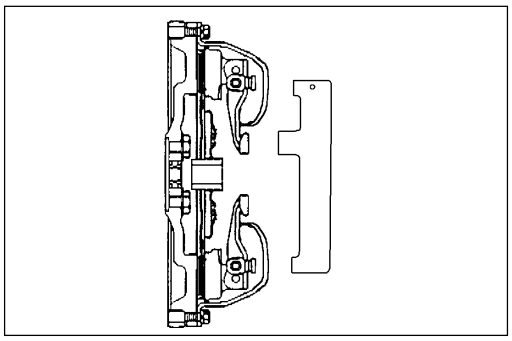
● Work before disassembly

Put alignment marks on all parts before disassembly.

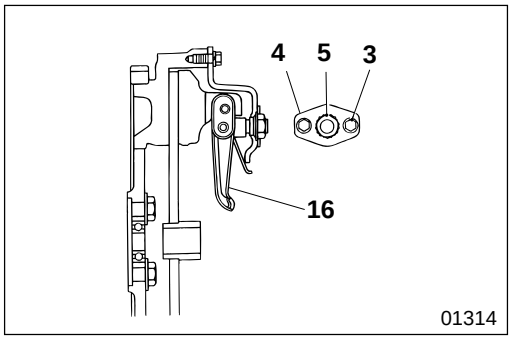
● Inspection and adjustment after assembly

(1) Measurement of release lever height

- Install the pressure plate and lever assembly using Ⓒa clutch master plate and Ⓒb clutch alignment arbor instead of clutch disc.
- Install Ⓒa clutch master plate so that identification mark "**6**" can be seen.

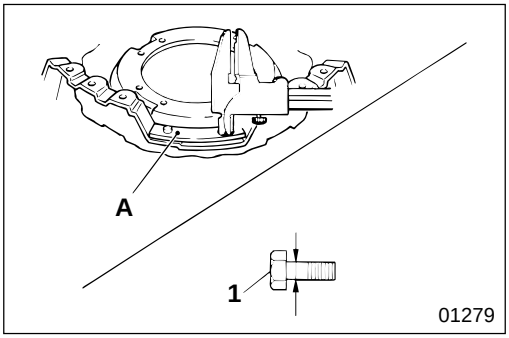


- Measure dimension **A** between Ⓒa clutch master plate and each upper surface of release levers **16** (four points).
- If the measured values deviate from the standard value, adjust as follows. Even if the measured values are within the standard value, if the relative difference among each measured value is 0.5 mm {0.020 in.} or more, adjust the heights, too.



(2) Adjustment of release lever height

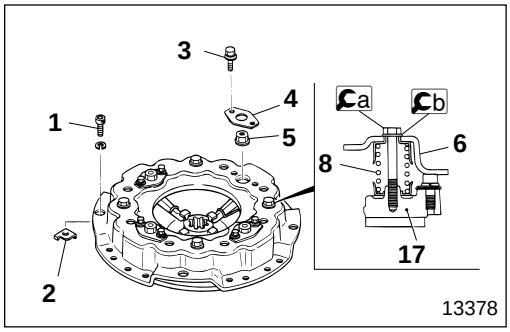
- Remove bolt **3** and lock plate **4**, and adjust the height by turning support nut **5**.
- After adjustment, install lock plate **4**, fasten support nut **5** and check the height of release lever **16**.



1 **A** **Clearance between strap bolt and strap plate**

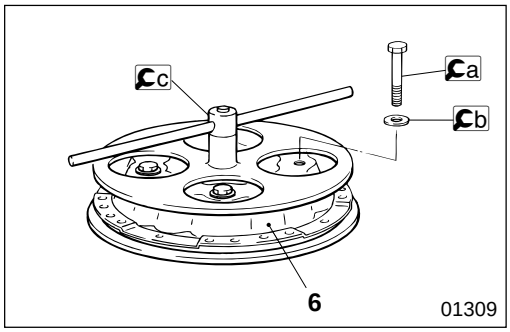
If the measured value is higher than the limit, replace the faulty parts.

A : Strap plate

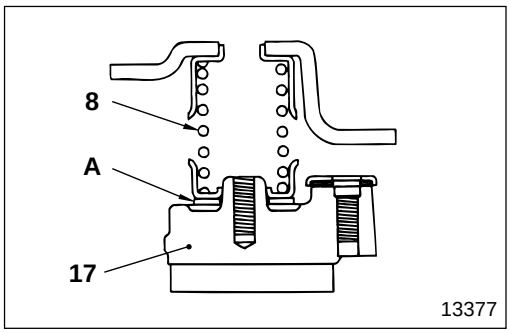


6 **Removal and installation of clutch cover**

- After fixing clutch cover **6** and pressure plate **17** using ca stopper bolt and cb washer, remove strap bolt **1**, washer **2**, lock bolt **3**, lock plate **4** and support nut **5**.



- Compress pressure spring **8** using cc clutch installer, and remove ca stopper bolt and cb washer.
- Gradually loosen cc clutch installer until pressure spring **8** is released, and remove clutch cover **6**.
- For installation, follow the removal sequence in reverse.



8 **Installation of pressure spring**

When grinding pressure plate **17** to correct it, insert adjusting washer **A**, equivalent to the amount of correction made by grinding, between the pressure plate and pressure spring **8**.

Amount of correction made by grinding	Thickness of adjusting washer

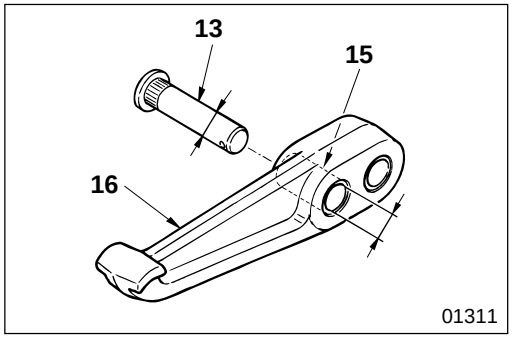
10 **14** **Clearance between support lever pin and bushing**

If the measured value is higher than the limit, replace the faulty parts.

NOTE

This inspection must be made with bushing 14 press-fitted in release lever 16.

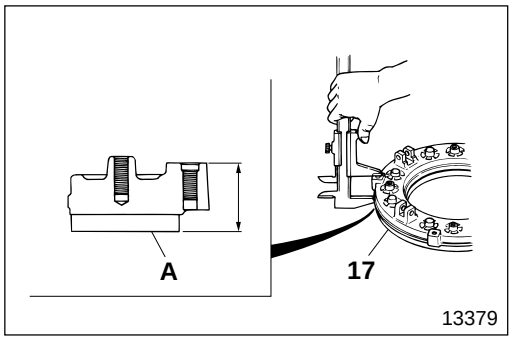


13 **15** **Clearance between release lever pin and bushing**

If the measured value is higher than the limit, replace the faulty parts.

NOTE

This inspection must be made with bushing 15 press-fitted in release lever 16.

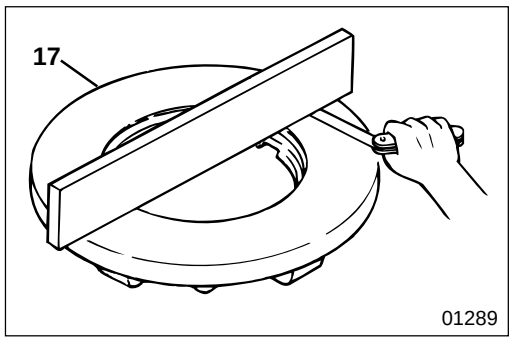


17 **Inspection of pressure plate**

(1) Thickness

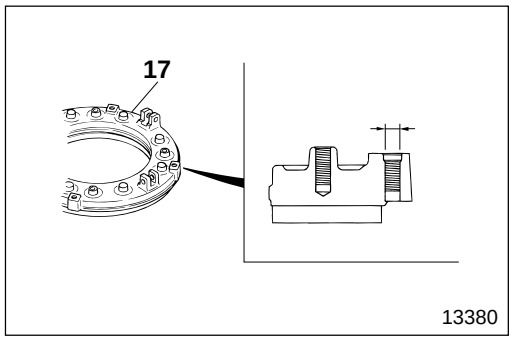
- Measure friction surface **A** of pressure plate **17** (measuring position must be within the maximum and minimum diameters), and if the measured value is lower than the limit, replace the pressure plate.

Maximum diameter	340 mm {13.4 in.}
Minimum diameter	250 mm {9.84 in.}



(2) Levelness

If the measured value is lower than the limit, replace pressure plate **17**.



(3) Inner diameter of fitting hole of strap bolt

If the measured value is higher than the limit, replace pressure plate **17**.

◆ Service procedure

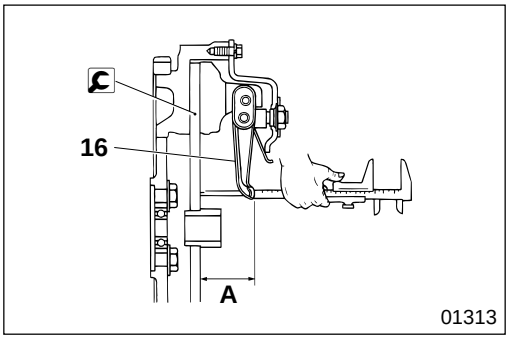
● Work before disassembly

Put alignment marks on all parts before disassembly.

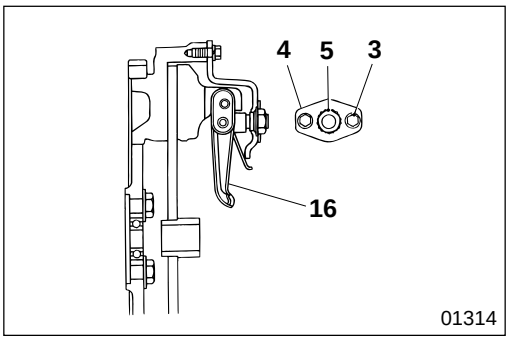
● Inspection and adjustment after assembly

(1) Measurement of release lever height

- Install the pressure plate and lever assembly using a clutch master plate and b clutch alignment arbor instead of clutch disc.
- Install a clutch master plate so that identification mark "**7**" can be seen.

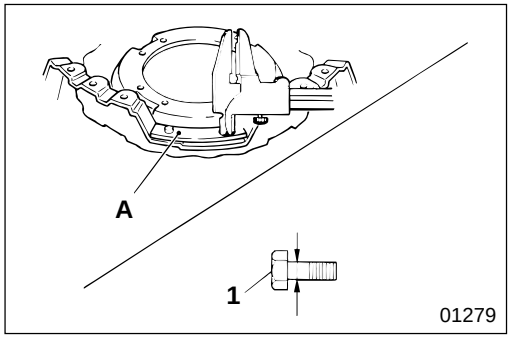


- Measure dimension **A** between clutch master plate and each upper surface of release levers **16** (four points).
- If the measured values deviate from the standard value, adjust as follows. Even if the measured values are within the standard value, if the relative difference among each measured value is 0.5 mm {0.020 in.} or more, adjust the heights, too.



(2) Adjustment of release lever height

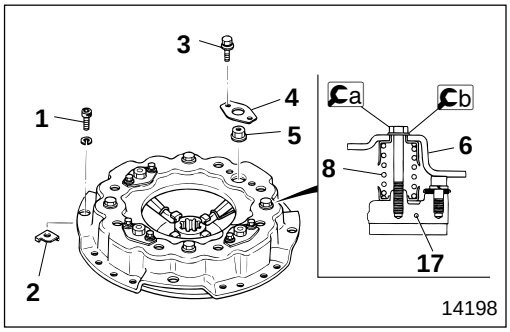
- Remove bolt **3** and lock plate **4**, and adjust the height by turning support nut **5**.
- After adjustment, install lock plate **4**, fasten support nut **5** and check the height of release lever **16**.



1 **A** **Clearance between strap bolt and strap plate**

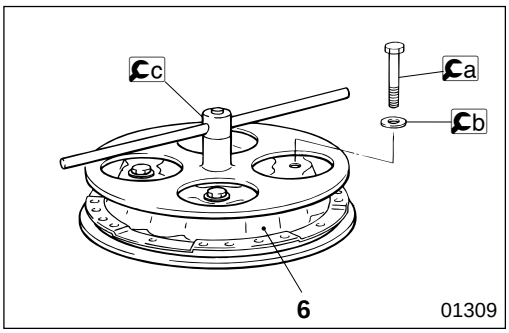
If the measured value is higher than the limit, replace the faulty parts.

A : Strap plate

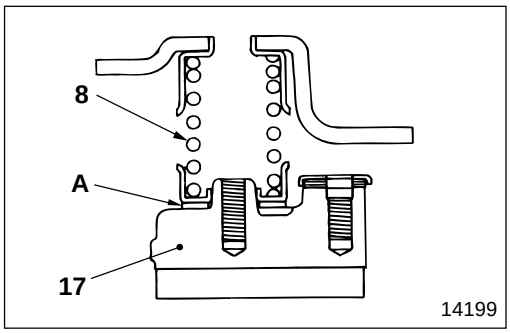


6 **Removal and installation of clutch cover**

- After fixing clutch cover **6** and pressure plate **17** using a stopper bolt and b washer, remove strap bolt **1**, washer **2**, lock bolt **3**, lock plate **4** and support nut **5**.



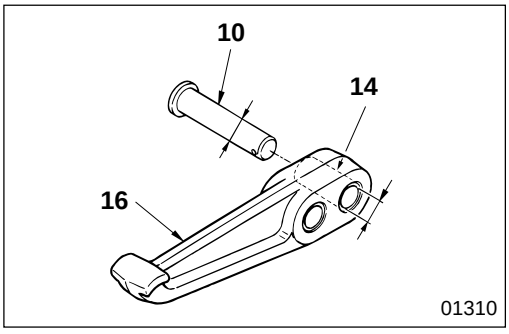
- Compress pressure spring **8** using c clutch installer, and remove a stopper bolt and b washer.
- Gradually loosen c clutch installer until pressure spring **8** is released, and remove clutch cover **6**.
- For installation, follow the removal sequence in reverse.



8 **Installation of pressure spring**

When grinding pressure plate **17** to correct it, insert adjusting washer **A**, equivalent to the amount of correction made by grinding, between the pressure plate and pressure spring **8**.

Amount of correction made by grinding	Thickness of adjusting washer
Less than 1 mm {0.039 in.}	Not required
1 to 2 mm {0.039 to 0.079 in.}	1.2 mm {0.047 in.}×1
2 to 3 mm {0.079 to 0.12 in.}	1.2 mm {0.047 in.}×2 or, 2.3 mm {0.091 in.}×1

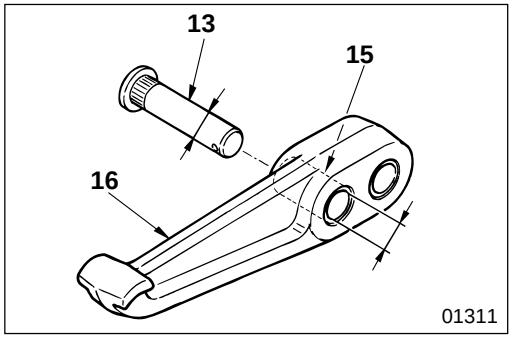


10 **14** **Clearance between support lever pin and bushing**

If the measured value is higher than the limit, replace the faulty parts.

NOTE

This inspection must be made with bushing 14 press-fitted in release lever 16.

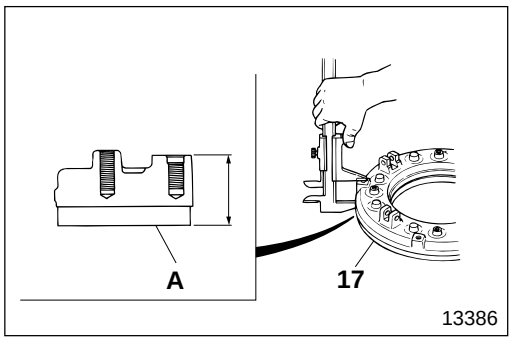


13 **15** **Clearance between release lever pin and bushing**

If the measured value is higher than the limit, replace the faulty parts.

NOTE

This inspection must be made with bushing 15 press-fitted in release lever 16.

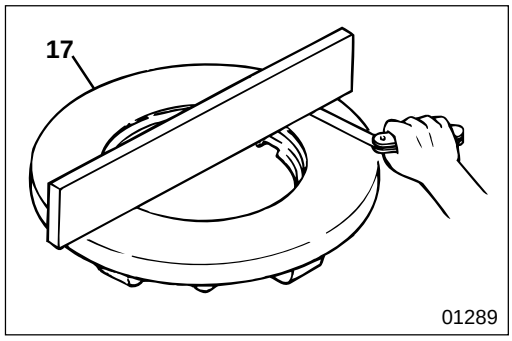


17 **Inspection of pressure plate**

(1) Thickness

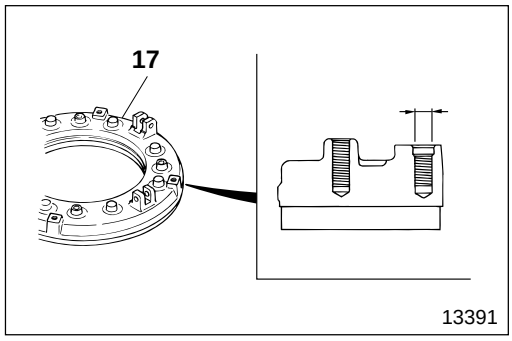
- Measure friction surface **A** of pressure plate **17** (measuring position must be within the maximum and minimum diameters), and if the measured value is lower than the limit, replace the pressure plate.

Maximum diameter	370 mm {14.6 in.}
Minimum diameter	240 mm {9.45 in.}



(2) Levelness

If the measured value is lower than the limit, replace pressure plate **17**.



(3) Inner diameter of fitting hole of strap bolt

If the measured value is higher then the limit, replace pressure plate **17**.

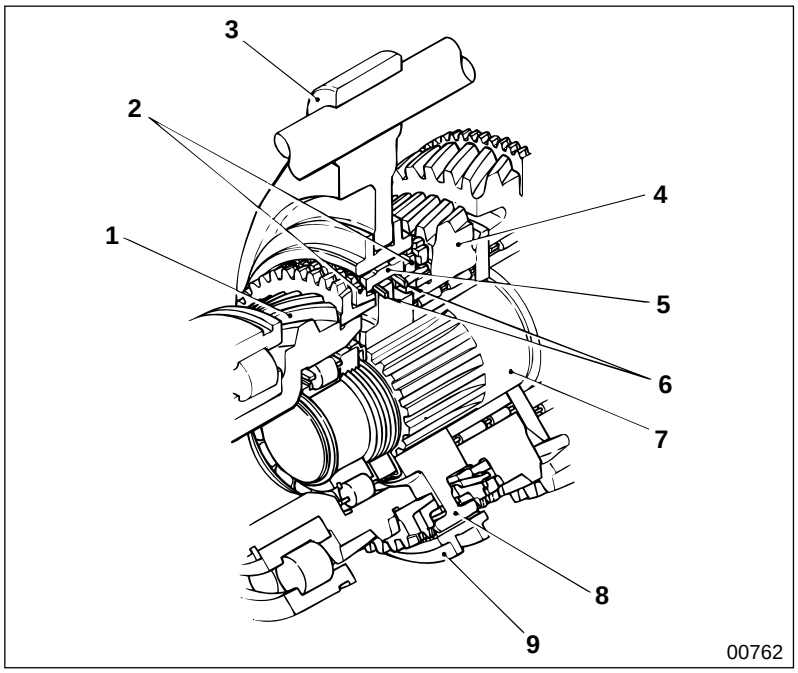
The transmission changes revolution and torque generated by the engine into those that match the vehicle's power requirement (driving force). Revolution and torque are increased or decreased by making a selection from several sets of engaged gears. The transmission uses an interlock mechanism to avoid double engagement.

Synchromesh Mechanism

This vehicle has two synchromesh mechanisms, a single cone type, and a double cone type, and uses the key system. The single or double cone type is used depending on the gear positions as shown below:

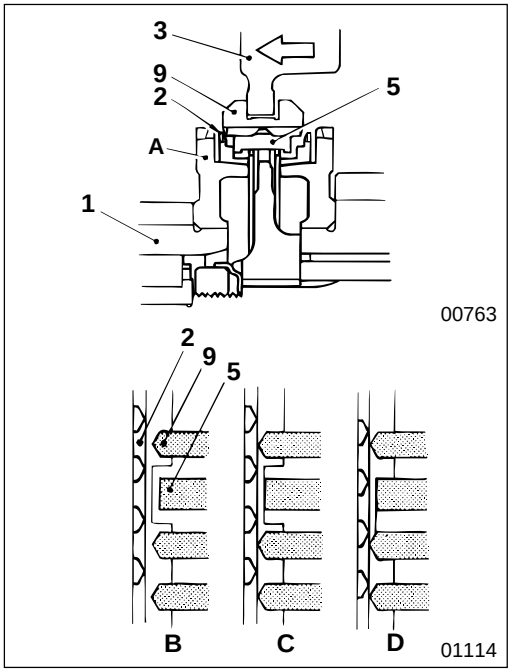
Transmission model / Synchromesh type	O/D	D/D
Single cone type	4th, 5th and 6th	5th, 6th
Double cone type	2nd and 3rd	2nd, 3rd and 4th

Single Cone Type

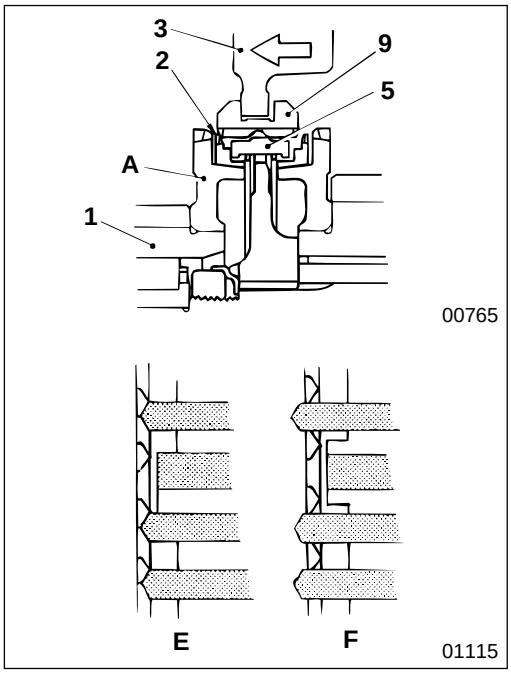


1 Drive pinion (Single cone type)
2 Synchronizer ring
3 4th and 5th shift fork
4 4th gear (Double cone type)
5 Shifting key
6 Shifting key spring
7 Mainshaft
8 Synchronizer hub
9 Synchronizer sleeve

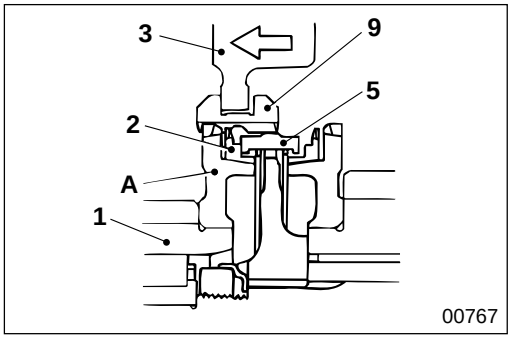
- The following descriptions are for 4th and 5th gear < O/D >
  The inside of synchronizer hub **8** engages the spline of mainshaft **7** and rotates with it. The outside of the synchronizer hub has a spline that engages synchronizer sleeve **9** and three keyways.
- Shifting keys **5** are inserted into these keyways. When the gear shift is in neutral, a protrusion in the center of each shifting key engages a groove inside the synchronizer sleeve and the shifting keys are pressed against the inside of the synchronizer sleeve by shifting key springs **6**.
- Synchronizer rings **2** are inserted into drive pinions **1** in the front and rear of synchronizer hub **8**, and the taper cone of 4th gear **4**.
- The internal tapers of synchronizer rings **2** have fine threads, and the outer splines engage synchronizer sleeve **9**. On the hub side of the synchronizer rings are three keyways in which the ends of shifting keys **5** are inserted. These keyways are wider than the width of the shifting keys.
- Synchronizer rings **2** rotate relative to synchronizer sleeve **9** by the amount of play of the keyways.



- When the gear shift is in neutral (Figure **B**), moving shift fork **3** in the direction of the arrow as illustrated, moves synchronizer sleeve **9** slightly to the left. At the same time, shifting key **5**, the central protrusion of which engages the synchronizer sleeve, moves to the left and presses synchronizer rings **2** against taper cone **A** of drive pinion **1**. (Figure **C**)
- When the taper surfaces of synchronizer rings **2** make contact with the taper cone of the drive pinion, the taper surfaces of the synchronizer rings act as cone clutches. This frictional torque rotates the synchronizer rings in the rotating direction of the drive pinion by the amount of play between shifting key **5** and the synchronizer rings. The spline chamfers of the synchronizer rings and the spline chamfer of synchronizer sleeve **9** are offset from each other. (Figure **D**)
- The disengagement direction of synchronizer rings **2** is defined by the speed of rotation of the synchronizer—sleeve **9**, and the synchronized—drive pinion **1**. When increasing the vehicle speed by shifting up, disengagement is made in the opposite direction to rotation, and when decreasing the vehicle speed by shifting down, disengagement is made in the rotating direction.

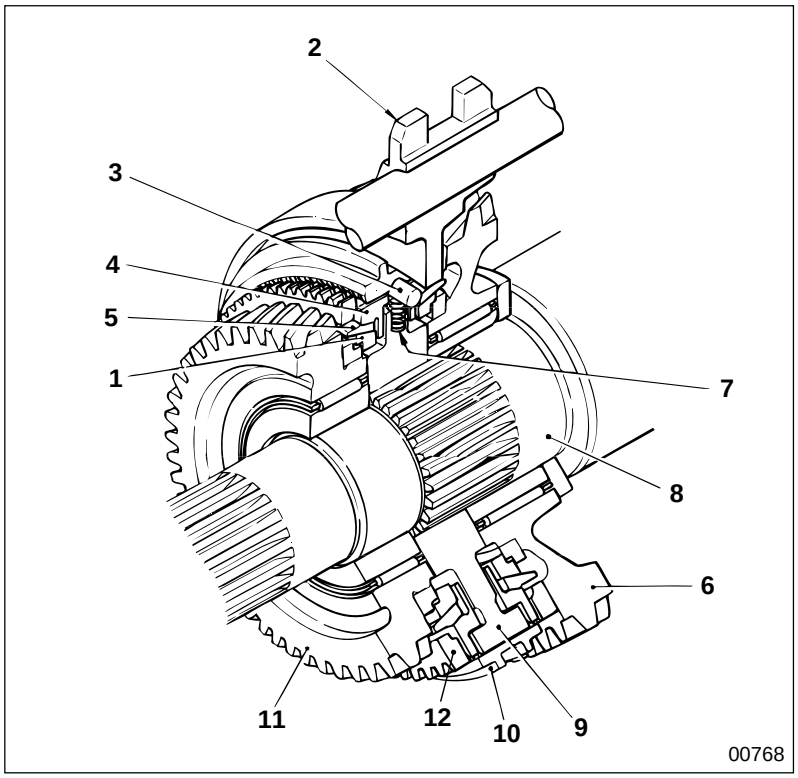


- When synchronizer sleeve **9** moves further to the left, synchronizer rings **2** prevent shifting key **5** from moving, and the synchronizer sleeve disengages from the protrusion of the shifting key.
- Since synchronizer rings **2** remain disengaged, the spline chamfer of synchronizer sleeve **9** presses the spline chamfers of the synchronizer rings, which in turn press the synchronizer rings against taper cone **A** of drive pinion **1**.
- As the frictional torque increases on the taper surfaces, the relative speed of the synchronizer and the synchronized gradually decreases.
  E : In synchronization
  F : After synchronization



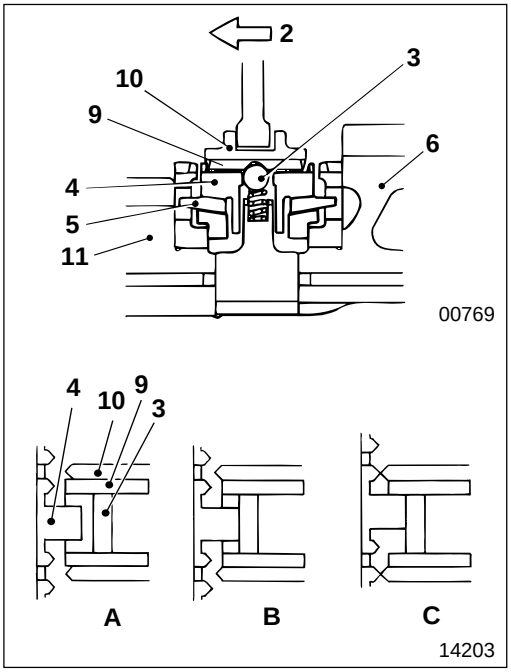
- When synchronizer sleeve **9** and drive pinion **1** rotate at the same speed, synchronizer rings **2** no longer prevent the synchronizer sleeve from moving, and the synchronizer sleeve moves further to the left and smoothly engages the spline of taper cone **A** of drive pinion **1**, transmitting the driving force.

Double Cone Type

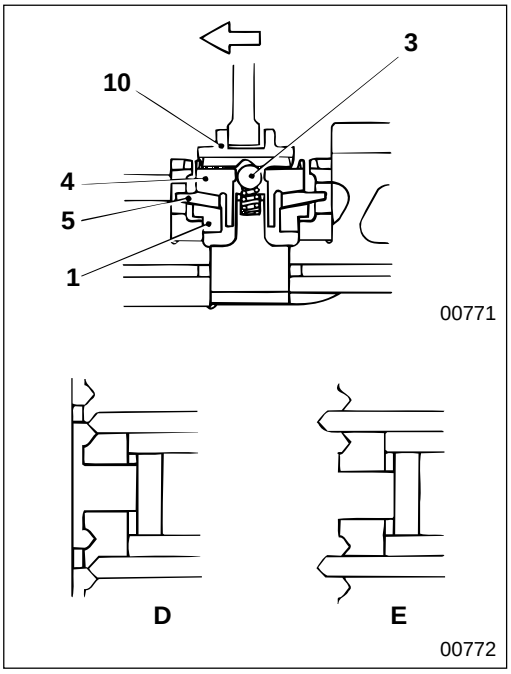


1 Synchronizer inner ring
2 2nd and 3rd shift fork
3 Shifting key
4 Synchronizer outer ring
5 Synchronizer center cone
6 2nd gear
7 Shifting key spring
8 Mainshaft
9 Synchronizer hub
10 Synchronizer sleeve
11 3rd gear
12 Dog clutch

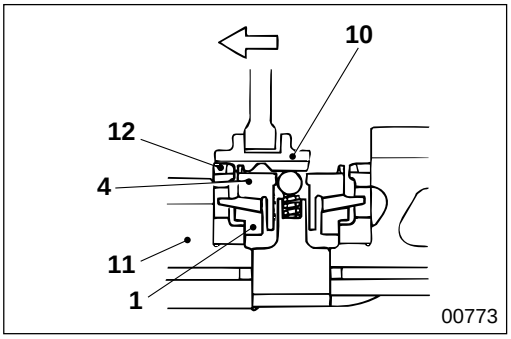
- The following descriptions are for 2nd and 3rd gear < O/D >
  The synchromesh structure and operation of the double cone type are basically the same as for the single cone type.
- Synchronizer center cone **5** is a taper cone independent of 2nd gear **6** and 3rd gear **11**, (both the inside and outside surfaces are tapered). The synchronizer center cone is between synchronizer inner ring **1** and synchronizer outer ring **4** to increase the synchronization capacity.
- Six protrusions on the outside of center cone **5** fit into corresponding gear holes, in the same manner as the taper cone of the single cone type. The center cone and the gear are installed as if integrated.
  Shifting key **3** is a cylinder installed so that the lengthwise direction of the cylinder is at right angles to the diameter direction of synchronizer hub **9**. Shifting key spring **7** is a coil spring inserted in a hole in the synchronizer hub, this spring presses the shifting key against the inside of synchronizer sleeve **10**.
- The 4th gear of the < O/D > model uses the double cone type; however, the structure of shifting key **3** and shifting key spring **7** is the same as for the single cone type.



- When the gear shift is in neutral (Figure **A**), moving shift fork **2** in the direction of the arrow as illustrated, moves synchronizer sleeve **10** slightly to the left. At the same time, shifting key **3**, the central protrusion of which engages the synchronizer sleeve, moves to the left and presses synchronizer outer ring **4** against synchronizer center cone **5**. (Figure **B**)
- When the taper surface of synchronizer outer ring **4** makes contact with the taper cone of synchronizer center cone **5**, the taper surface of the synchronizer outer ring acts as a cone clutch. This frictional torque rotates the synchronizer outer ring in the rotating direction of 3rd gear **11** by the amount of play between the synchronizer outer ring and synchronizer hub **9**. The spline chamfer of the synchronizer outer ring and the spline chamfer of synchronizer sleeve **10** are offset from each other. (Figure **C**)
- The disengagement direction of synchronizer outer ring **4** is defined by the speed of rotation of the synchronizer—the sleeve, and the synchronized—3rd gear **11**. When increasing the vehicle speed by shifting up, disengagement is made in the opposite direction to rotation, and when decreasing the vehicle speed by shifting down, disengagement is made in the rotating direction.



- When synchronizer sleeve **10** moves further to the left, synchronizer outer ring **4** prevents shifting key **3** from moving, and the synchronizer sleeve disengages from the protrusion of the shifting key.
- Since synchronizer outer ring **4** remains disengaged, the spline chamfer of synchronizer sleeve **10** presses the spline chamfer of the synchronizer outer ring, which in turn presses the synchronizer outer ring against the taper cone of synchronizer center cone **5**, and the frictional torque acts on the taper surface.
- As the frictional torque increases on the taper surface of synchronizer inner ring **1**, the relative speed of the synchronizer and the synchronized gradually decreases. The frictional torque acts on both sides of the synchronizer center cone. The double cone type has greater capacity for synchronization than the single cone type.
  D : In synchronization
  E : After synchronization



- When synchronizer sleeve **10** and 3rd gear **11** rotate at the same speed, synchronizer outer ring **4** no longer prevents the synchronizer sleeve from moving and the synchronizer sleeve moves further to the left and smoothly engages the spline of dog clutch **12** of the 3rd gear, transmitting the driving force.

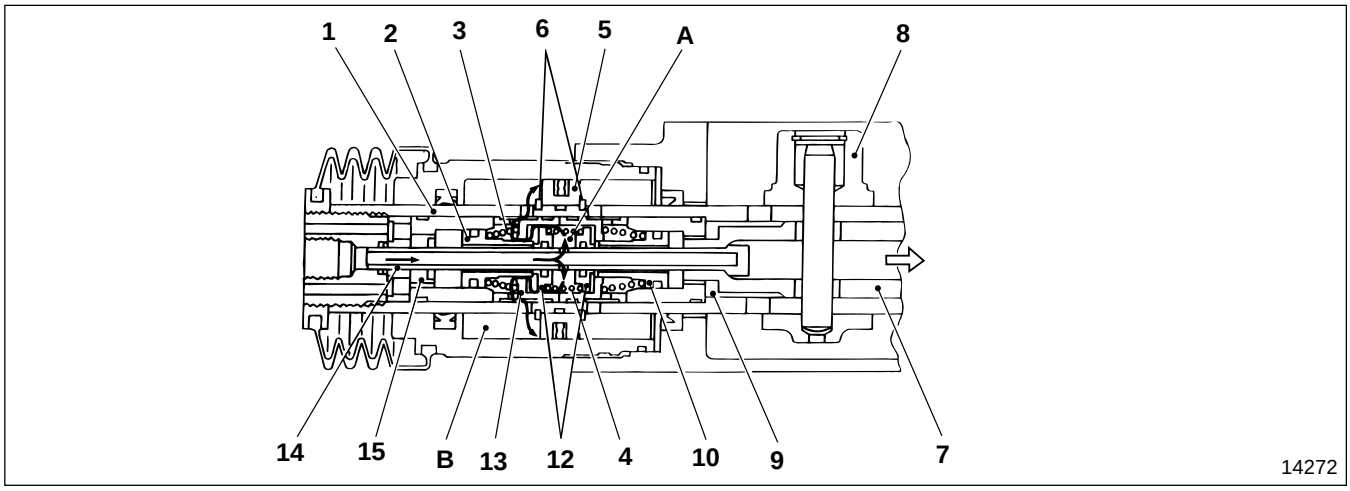
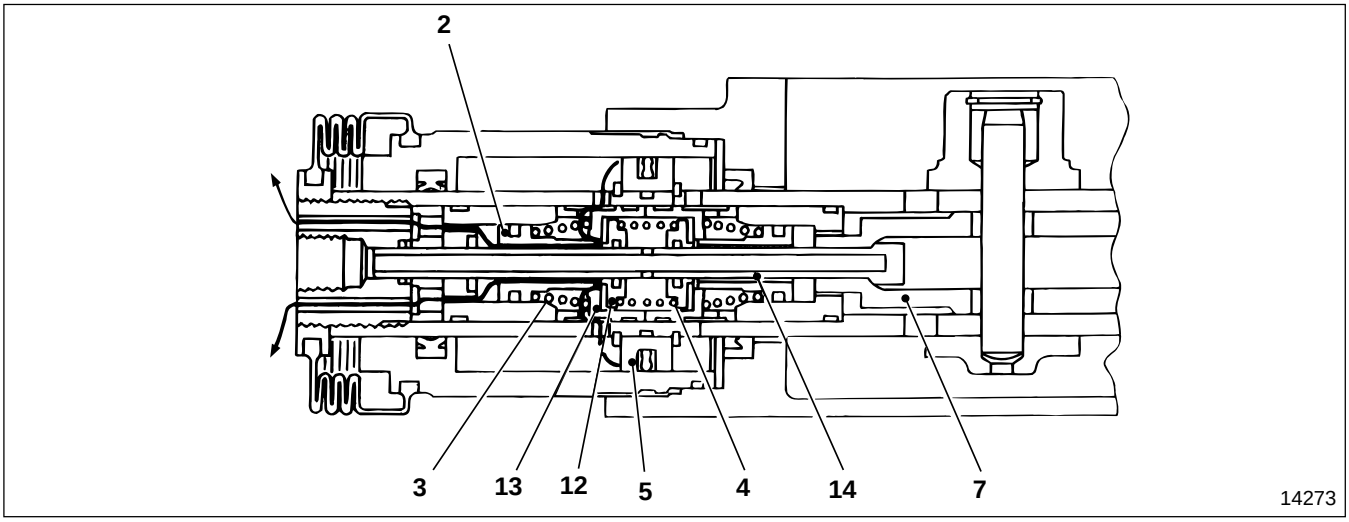
A : Primary side chamber
B : Secondary side chamber



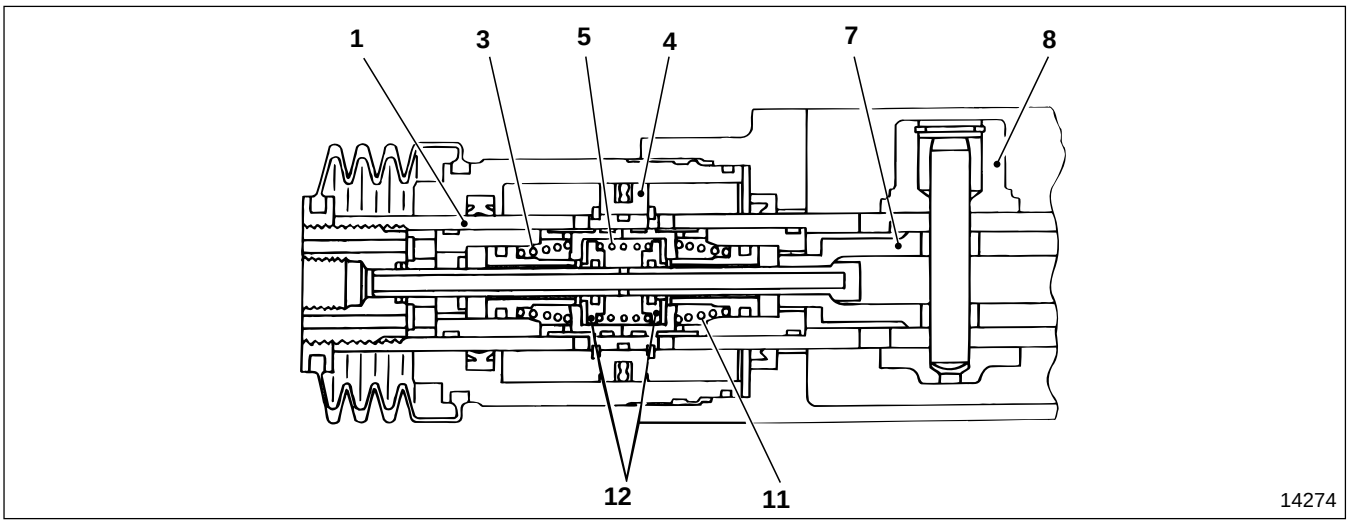
When activated

- When actuating rod **7** is moved in the direction of the arrow as illustrated, shifter rod **1** and the actuating rod move relative to this movement.
  Valve lifter **2** presses No.3 spring **3** against valve seal **12** to overcome the combined repercussive forces of the compressed air acting on the valve seal and No.2 spring **4**. The valve seal separates from valve seat **13**, and the compressed air supplied to primary side chamber **A** is let into secondary side chamber **B** via the opening between the valve seat and the valve seal. The compressed air flows into the cylinder through the hole and groove of the valve seal and the vent hole of shifter rod **1** to put pressure on piston **5**, generating output.
- The output given to piston **5** is transmitted to shifter rod **1** via retaining ring **6** to assist striker **8** which is fixed on the shifter rod. This operates the shift fork on the transmission side, shifting the gears. Thus, gear shifting is completed.
- When the power shift operates in the direction of the arrow as illustrated, the input from the gear shift lever is transmitted by actuating rod **7** via cap **9**, pipe **14**, and retainer **15** fixed on retaining ring **16**. For operation in the opposite direction, all operations are the same in principle as in the direction of the arrow as illustrated, except that the end of the cap, fixed on the end of the actuating rod, presses valve lifter **10** directly.



When releasing

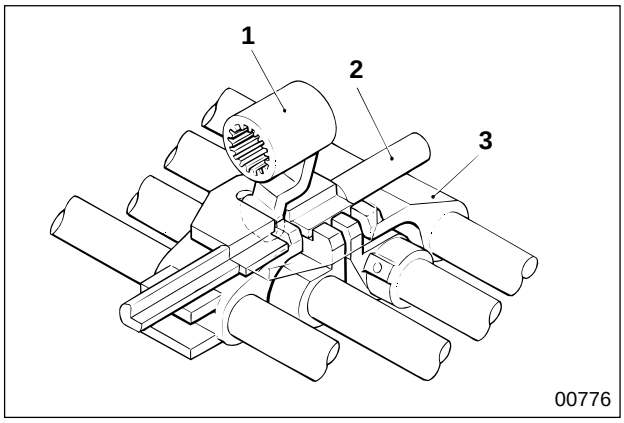
- When gear shifting is completed and the input is released, actuating rod **7** is returned to the valve center position (the condition before operation) by the combined repercussive forces of the compressed air of valve lifter **2**, the steel ball, and valve springs **3**, **4**.
  As the valve lifter returns, valve seal **12** seats against valve seat **13**, cutting off the flow of compressed air from primary side chamber **A** to secondary side chamber **B**. As the input rod returns, clearance is generated between the valve lifter and the valve seal.
- The compressed air in the cylinder of secondary side chamber **B** is discharged into the atmosphere through the clearance between valve lifter **2** and pipe **14**. This eliminates the pressure difference between the chambers on both sides of piston **5**, so output is lost.



When not operating (non-boosting)

- To operate the power shift, that is, to open the valve and let the compressed air into the output chamber, actuating rod **7** on the input side and shifter rod **1** on the output side must generate relative disengagement.
- When the operating force is transmitted from the gear shift lever to actuating rod **7**, and the resistance on the transmission side is less than the combined repercussive forces working on the relative disengagement of the input side and output side (repercussive forces of No.1 to 3 springs, **3**, **4**, **11**; pressure on valve seal **12**; and sliding resistance on various parts), the mechanism, from the actuating rod to striker **8**, is integrated and does not generate relative disengagement. Therefore, the valve does not open, and without boosting operation, piston **5** moves in the cylinder to shift gears.

Interlock Mechanism



In the interlock mechanism, the rail beneath interlock plate **2** locks jaws **3**, (apart from the jaws shifted by gear shift slide lever **1**), preventing double engagement of gears.

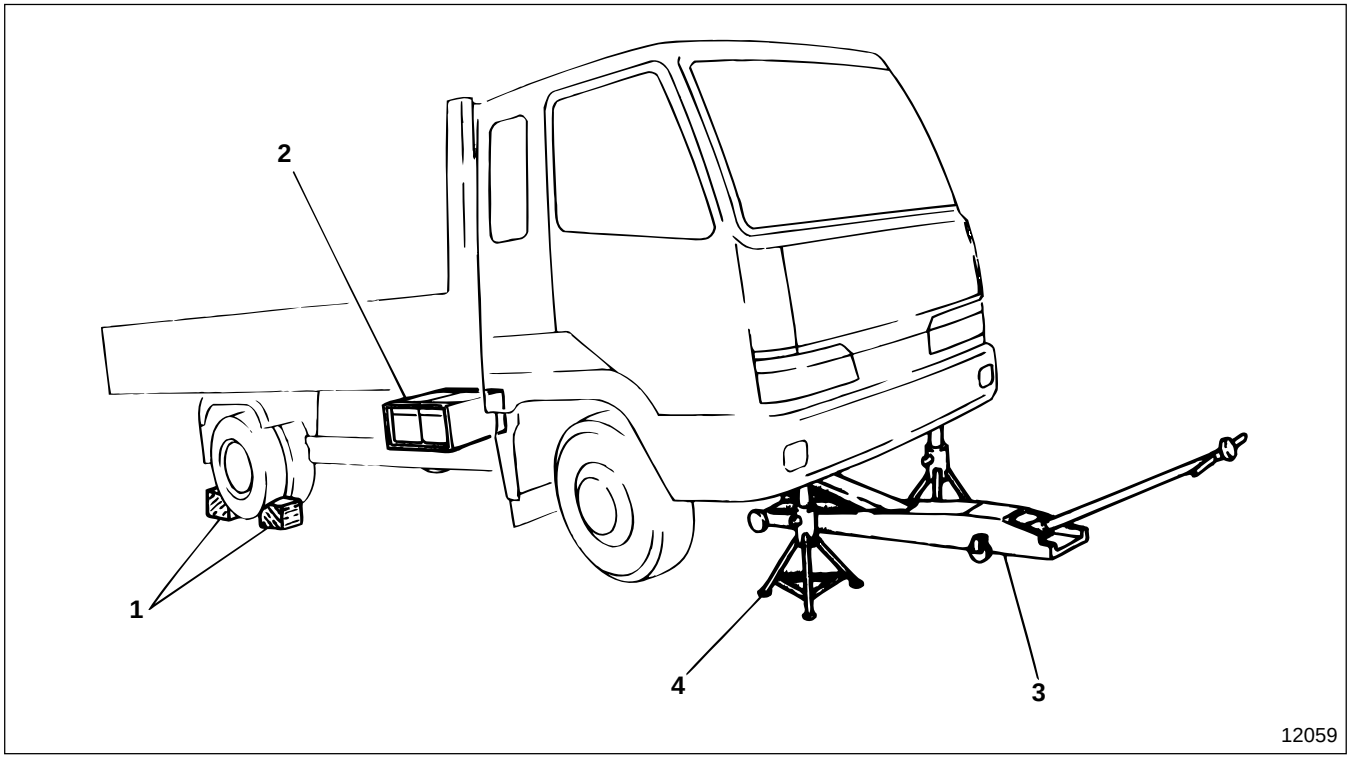
WORK BEFORE REMOVAL AND INSTALLATION OF TRANSMISSION ASSEMBLY



● **Work sequence before removal**

1 Place wheel chocks.
2 Disconnect negative battery cable. Gr 54
3 Jack up the front axle on a garage jack.
4 Support the front frame on rigid racks.

WARNING⚠

- **Since the parking brake will be removed, naturally it cannot be used. Therefore, you must chock the wheels securely so the vehicle does not move.**
- **Do not remove the chocks until the entire operation is completed.**
- **Supporting a vehicle on a garage jack only is extremely dangerous, so always support the frame on rigid racks.**
- **Leave the garage jack and rigid racks in place until the entire operation is completed. Never remove them during the operation.**

CAUTION⚠

Keep the transmission in neutral throughout the operation.

● **Work sequence after installation**

Follow the work sequence before removal in reverse.

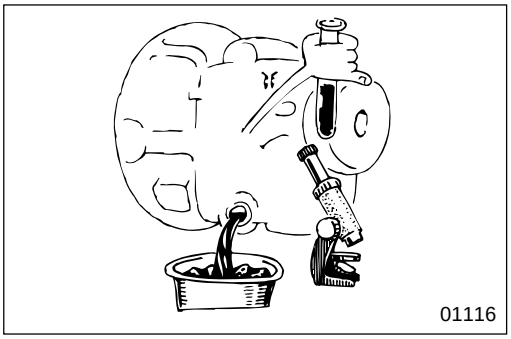
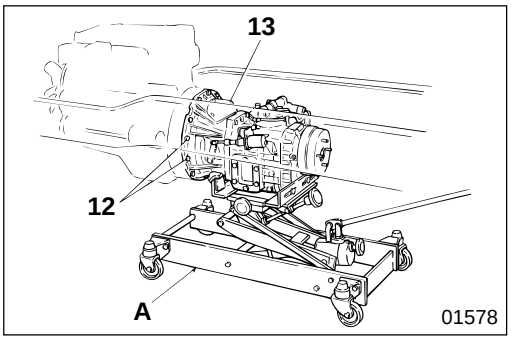
◆ Service procedure



● Oil change

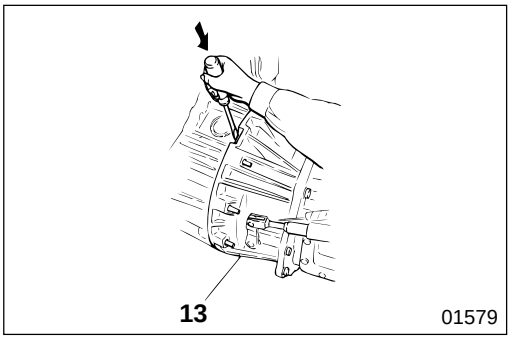
[Draining]
- When draining oil, check the quantity and quality of oil, especially for small pieces of metal and metal dust.
- Clean drain plug **9** before reinstalling it because it is magnetic.

[Filling]
- Check that drain plugs **10**, **11** are tightened at specified torque.
- Pour in gear oil until the oil overflows from the inspection hole. (For oil quantity, see specifications.)



12 Removal of transmission mounting nut or bolt

- Support transmission assembly **13** on transmission jack **A**.
- Tighten transmission mounting nuts or bolts **12**.

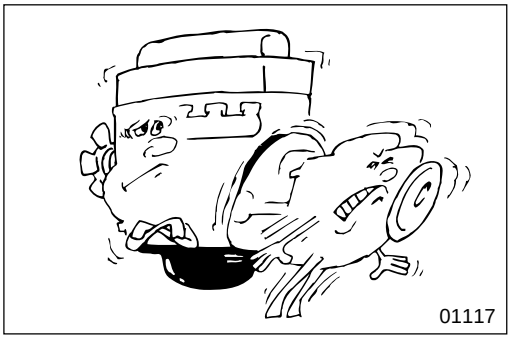


13 Transmission assembly

[Removal]
- Insert a screwdriver into the three removal grooves and pry transmission assembly **13** from the engine.

CAUTION⚠

Make sure that you remove hoses and cables before starting service operations.

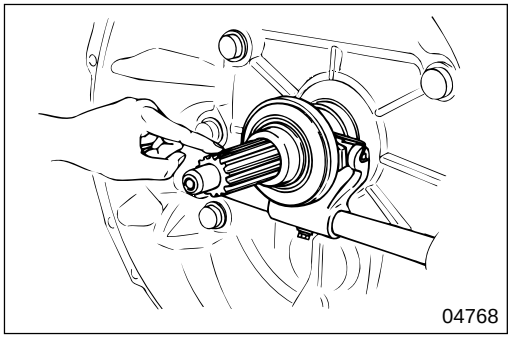


- Move transmission assembly **13** backward until the spline of the drive pinion is detached from the clutch.

CAUTION⚠

Make sure that you pull transmission assembly 13 out in a straight line. If you seesaw the transmission assembly violently, you will damage the spline that connects the drive pinion and the clutch.

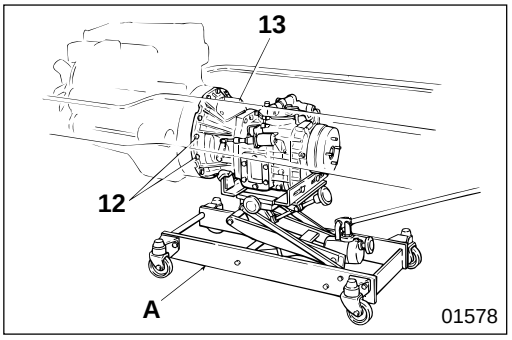
REMOVAL AND INSTALLATION OF TRANSMISSION ASSEMBLY



[Installation]
- Check the spline of the drive pinion for rust.
- If rust is found, remove it using a wire brush.
- Rub grease onto the clutch disc sliding surfaces of the drive pinion using your hand.

CAUTION

Make sure that you apply only the necessary amount of grease because too much grease would drip and cause clutch slip.



- Support transmission assembly **13** on transmission jack **A**, and insert the transmission assembly into the pilot bearing of the flywheel paying attention to the drive pinion spline.
- Tighten transmission mounting nuts or bolts **12** at specified torque.

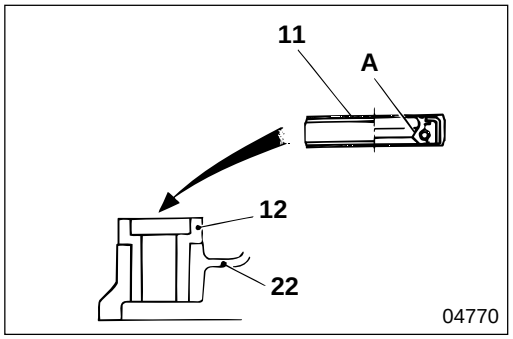
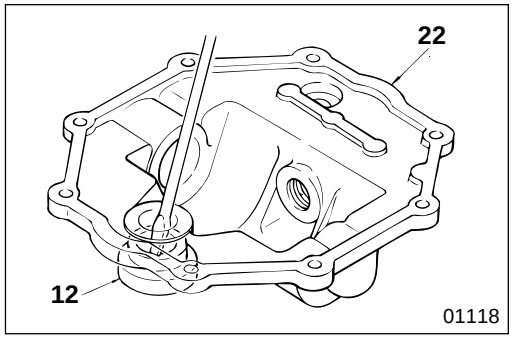
◆ Service procedure



11 Installation of oil seal

- Apply grease to lip area **A** of oil seal **11**.
- Press-fit oil seal **11** into bushing **12** in the direction as illustrated.



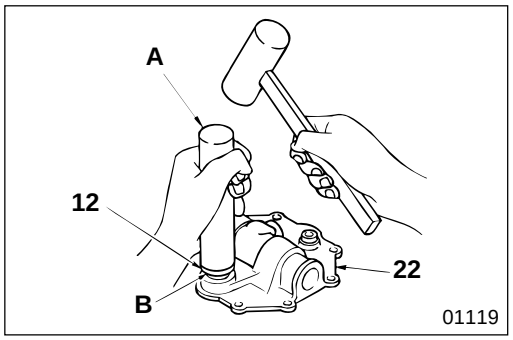
12 Bushing

[Removal]

Remove bushing **12** from selector lever case **22** using a screwdriver.

CAUTION

Be careful not to damage selector lever case 22.

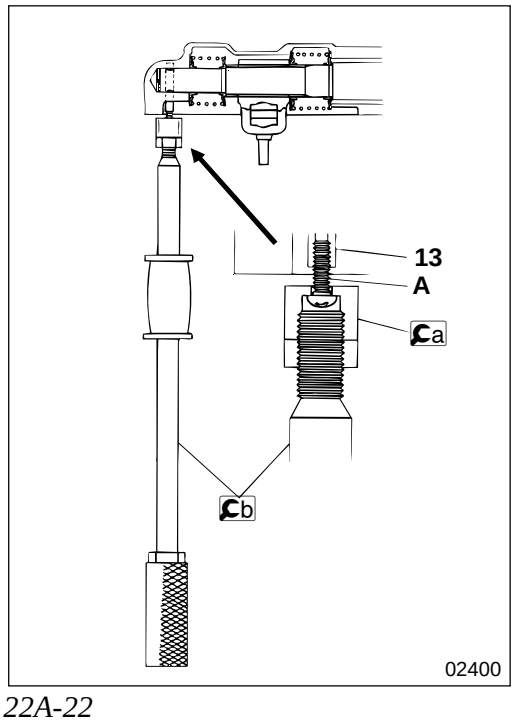


[Installation]

- Clean the inner surface of selector lever case **22**.
- Press-fit bushing **12** into selector lever case **22** using bar **A** (approximately ø40 mm {1.57 in.}).
- When press-fitting bushing **12**, take care not to damage selector lever case **22**.
- After press-fitting, apply sealant to press-fitted side **B** of bushing **12**.

CAUTION

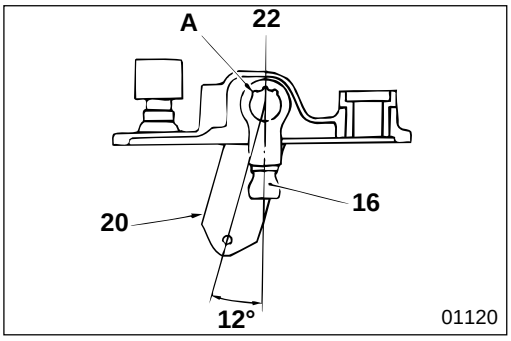
Prevent sealant from sticking to the inner surface of bushing 12.



13 Removal of spring pin

- Tap spring pin **13** using an M4 tap.
- Insert Ca spring pin puller with an M4 thread **A** of appropriate length into spring pin **13**.
- Position Cb reverse shaft puller on Ca spring pin puller.
- Remove spring pin **13** from selector lever case **22** using Ca spring pin puller and Cb reverse shaft puller.

< Without Power Shift >



16 **20** **Installation of gear shift slide lever and gear shift lever**

When you install gear shift slide lever **16** in gear shift lever **20**, position spline **A** so that the angle between the slide lever and the shift lever is as illustrated.

◆ Service Procedure

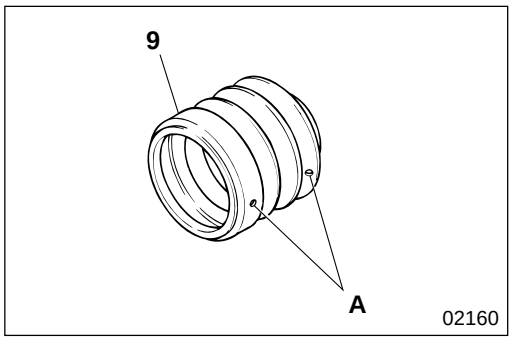
● Inspection before disassembly

(1) Apply 735 kPa {105 psi, 7.5 kgf/cm^2} of pressure to the power shift assembly from the connector, check the airtightness when not operating (valve in neutral), and when operating valve is pressed and pulled. If the measured value deviates from the standard value, replace the faulty parts.

Maintenance item	Standard value	
Airtightness when not operating	Decrease of pressure after 15 seconds	9.8 kPa {1.4 psi, 0.1 kgf/cm^2}
Airtightness when operating		49 kPa {7.1 psi, 0.5 kgf/cm^2}

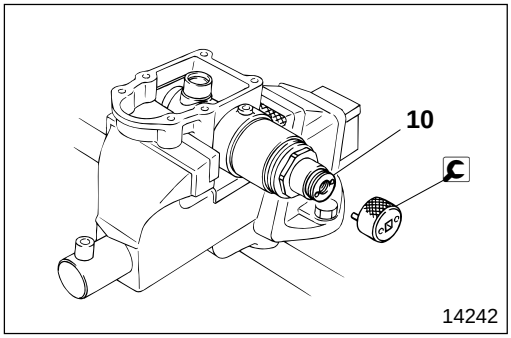
(2) Measure the sliding resistance in the disengagement direction. If the measured value deviates from the standard value, replace the faulty parts, or grease them.

Maintenance item	Standard value
Resistance in shifting direction	39 N {8.8 lbf, 4 kgf}

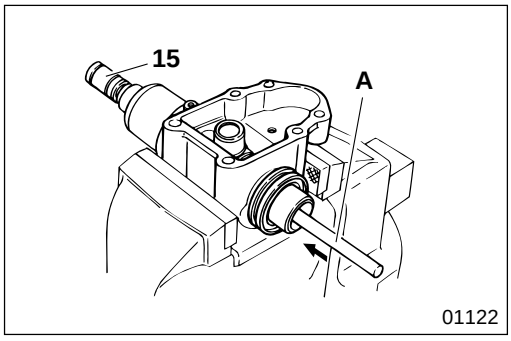


9 **Installation of boot**

When you install boot **9** on housing **52**, point drain holes **A** downward.



10 **Removal and installation of connector**

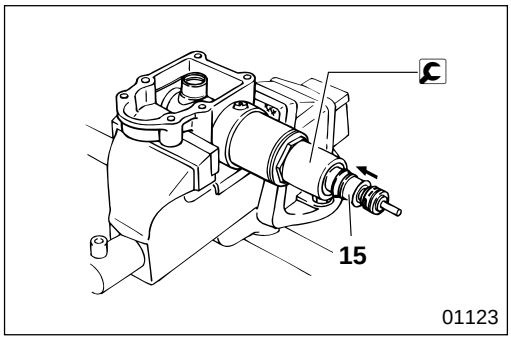


15 **Valve assembly**

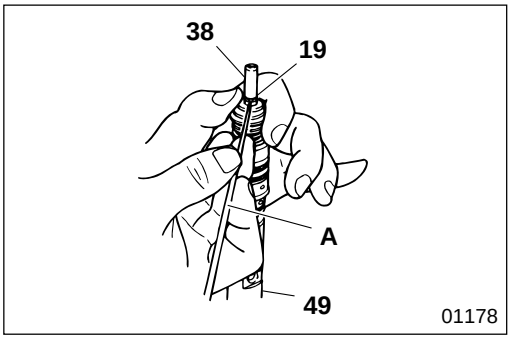
[Removal]
Gently drive valve assembly **15** out from the shifter rod from the lever side using bar **A**.

CAUTION

Do not drive valve assembly 15 too hard or you will damage the valve parts.



[Installation]
- Apply grease to valve assembly **15**.
- Install valve assembly **15** into the shifter rod using guide, taking care not to damage the seals.



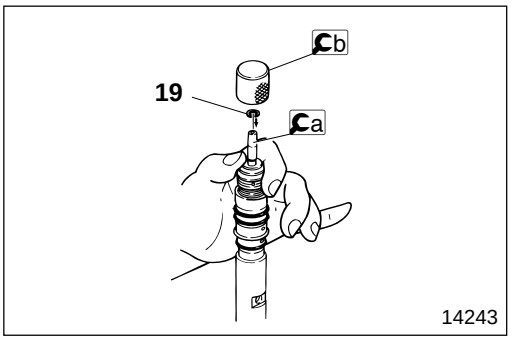
19 **Retaining ring**

[Removal]

- Hold shifter rod **49** in a vise, taking care not to damage the shifter rod.
- Remove retaining ring **19** from pipe **38** using bar **A** as illustrated.

CAUTION

- **After removing retaining ring 19, you can remove all the valve parts.**
- **Keep the valve parts in order to avoid mix ups when installing.**



[Installation]

- Install the valve parts on pipe **38**.
- Install a insert tool on pipe **38** end.
- Insert retaining ring **19** into pipe **38** groove using b insert tool.

CAUTION

Be careful not to apply excessive force to retaining ring 19 when you insert it.

◆ Service procedure

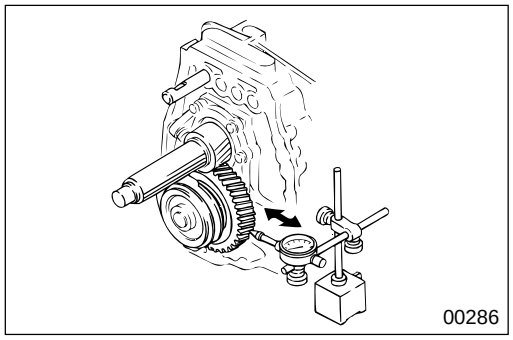
● Inspection before disassembly

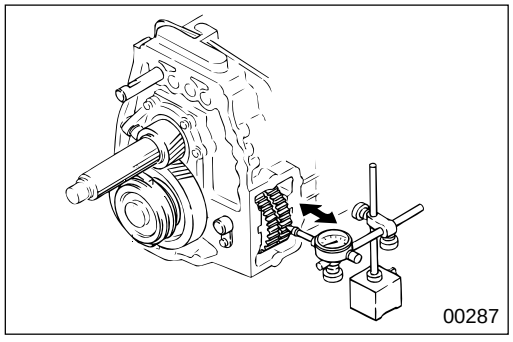
(1) End play of various gears

- If the measured value is higher than the limit, replace the faulty parts.
- Reinspect play after assembly to check that the measured value is within the limit.



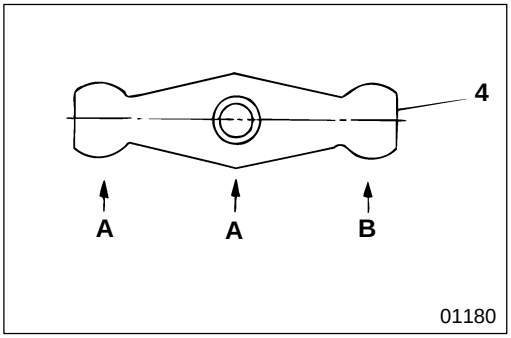
(2) Play of countershaft O/D gear in the diameter direction

- If the measured value is higher than the limit, replace the faulty parts.
- Reinspect play after assembly to check that the measured value is within the limit.



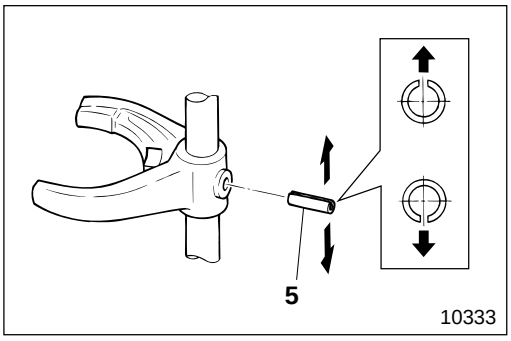
(3) Play of reverse ilder gear in the diameter direction

- If the measured value is higher than the limit, replace the faulty parts.
- Reinspect play after assembly to check that the measured value is within the limit.



4 Bend of O/D shift lever

If bend **B** exeeds the limit on the basis of illustrated **A - A**, replace O/D shift lever **4**.

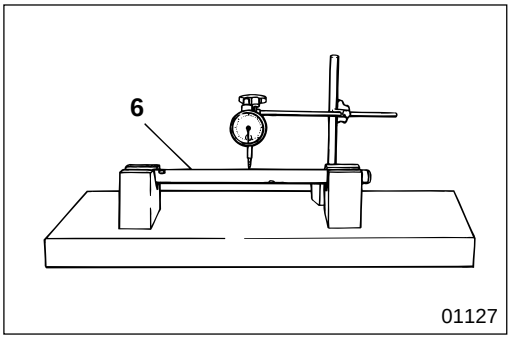


5 Installation of spring pin

Install spring pin **5** in O/D gear shift fork **7** in the direction as illustrated.

CAUTION

Make sure you do not drive in spring pin 5 fully, leave 0 to 0.5 mm {0 to 0.020 in.} outside to prevent them from slipping out.

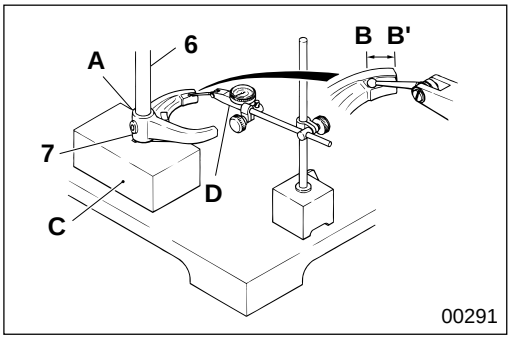


6 Bend of O/D shift rail C

If the measured value is higher than the limit, correct or replace O/D shift rail **C6**.

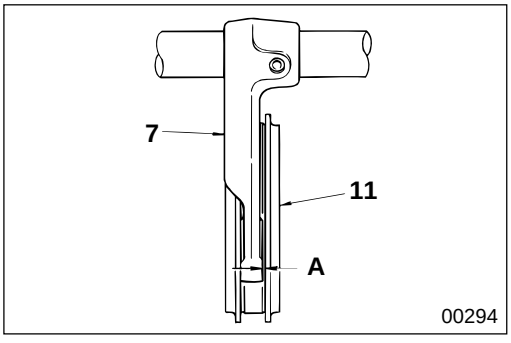
NOTE

Read the dial gauge after turning O/D shift rail C6 one full revolution. The bend is one half of the indicated value.



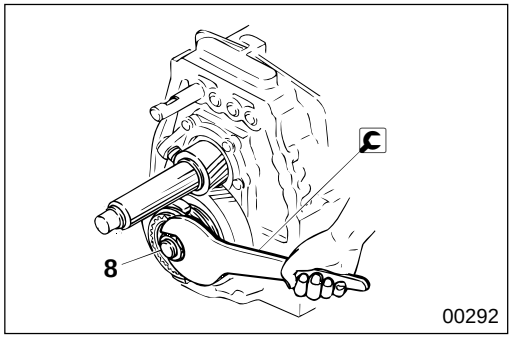
7 Tilt of O/D gear shift fork claw

- Measure the tilt (difference between **B** and **B'**) of claw **B-B'** against hole **A** of O/D shift rail C**6** of O/D gear shift fork **7** with the shift rail upright.
- If the measured value is higher than the limit, replace gear shift fork **7**.
  C : V-block
  D : Dial gauge



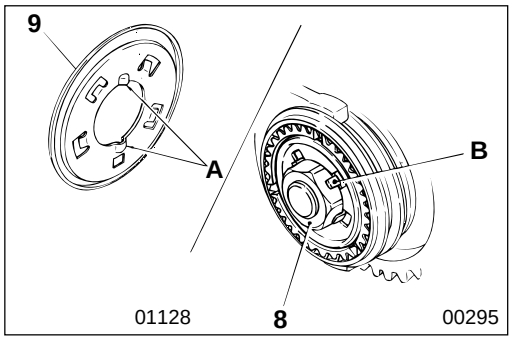
7 11 Clearance between O/D gear shift fork and synchronizer sleeve

- Measure clearance **A** between O/D gear shift fork **7** and synchronizer sleeve **11**.
- If the measured value is higher than the limit, replace the faulty parts.



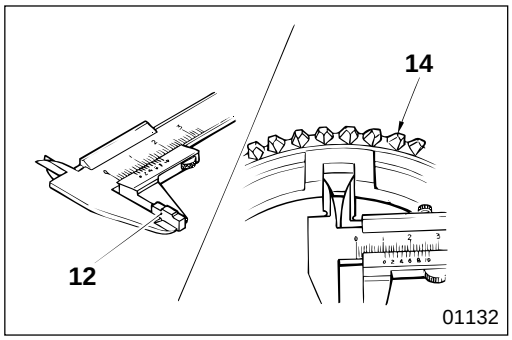
8 **Removal and installation of countershaft rear lock nut**

Have transmissions engaged in double to lock countershaft for this work.



9 **Installation of shifting key retainer**

- Install so that shifting key retainer **9** protrusions **A** (at 2 places) rest in recessions provided on synchronizer hub.
- After tightening of lock nut, caulk the areas with slits **B** at 4 places of shifting retainer, toward lock nut **8**.

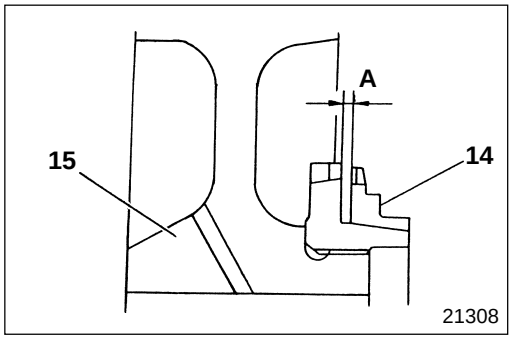


10 **to** **15** **Synchromesh mechanism and countershaft O/D gear assembly**

[Inspection]

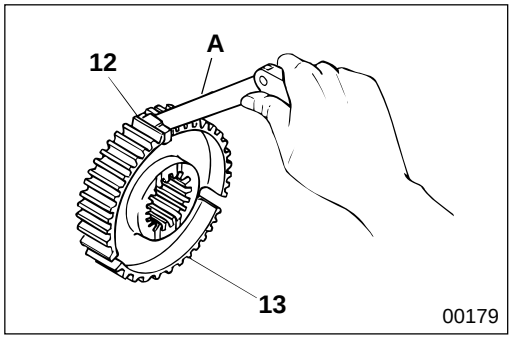
(1) Clearance between synchronizer ring 14 and shifting key 12.

If the measured value is higher than the limit, replace the faulty parts.



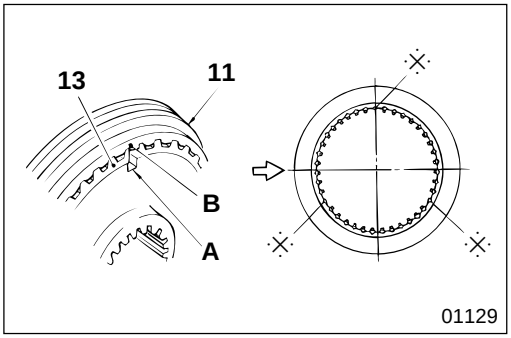
(2) Clearance between synchronizer ring 14 and countershaft O/D gear assembly 15

- Measure clearance **A** between synchronizer ring **14** and the gear cone of countershaft O/D gear assembly **15**.
- When measuring this value, press synchronizer ring **14** evenly, and measure all around the circumference.
- If the measured value is lower than the limit, replace the faulty parts.



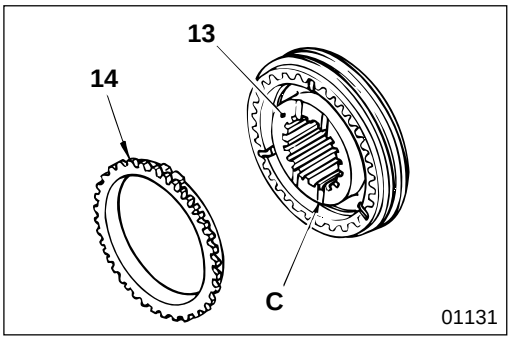
(3) Clearance between shifting key 12 and synchronizer hub 13

If the measured value is higher than the limit, replace the faulty parts.
A : Feeler gauge

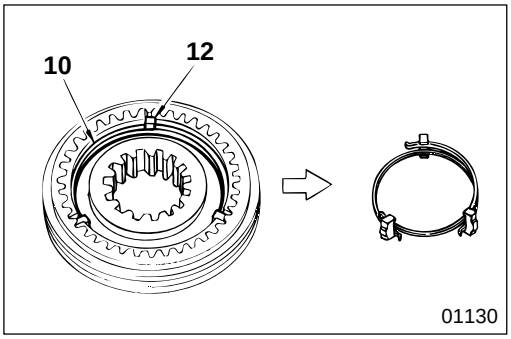


[Installation]

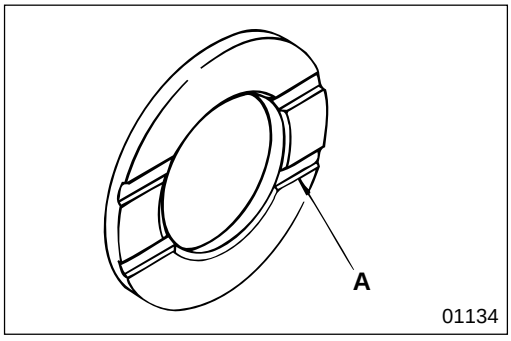
- Align the three keyways **A** of synchronizer hub **13** with the three stub teeth **B** (illustrated by ⋇ mark) of synchronizer sleeve **11** to install the synchronizer hub.
- To reassemble synchronizer hub **13** and synchronizer sleeve **11**, align the alignment marks made during disassembly.



- Assemble synchronizer ring **14** on synchronizer hub **13** with the keyway aligned to the side where oil groove **C** is located.

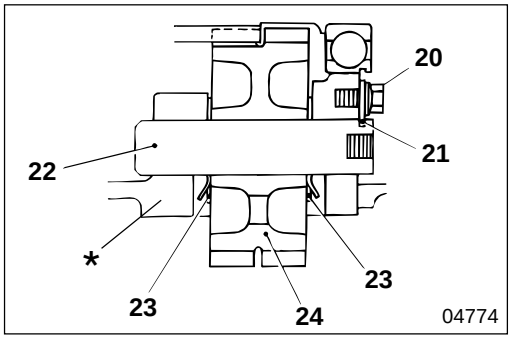


- Insert shifting **12** into the keyway.
- Install shifting key spring **10** so that its opening is offset from the one of the shifting key.
- Make sure that the openings of shifting key springs do not align with each other.



17 Installation of thrust washer

Install with the side having oil grooves **A** facing the side of gear.



20 to 24 Assembly of reverse idler gear

- Install reverse shaft gear side washer **23** and reverse idler gear **24** in trasmission body *****.
- Install reverse ilder shaft **22** in transmission body ***** using a plastic-headed mallet.
- Install reverse shaft lock piece **21** in transmission body ***** with mounting bolt **20**.

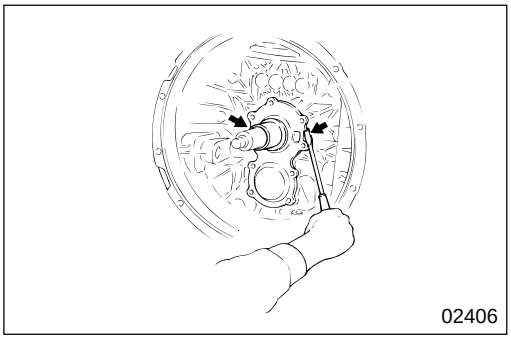
2 Installation of oil seal

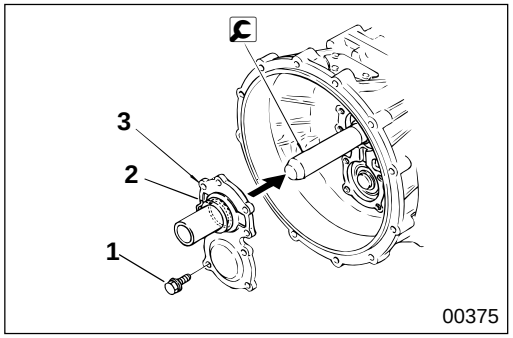
- Apply grease to lip area **A** of oil seal **2**.
- Press-fit oil seal **2** into front bearing retainer **3** in the direction as illustrated using oil seal installer.



02406

3 Front bearing retainer

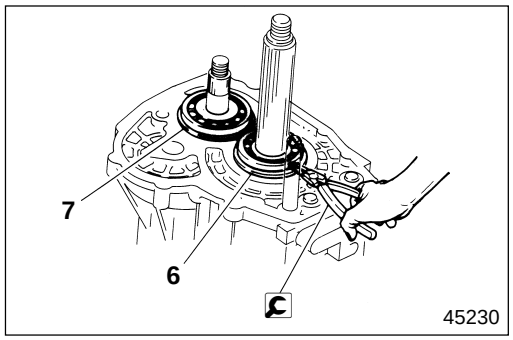
[Removal]



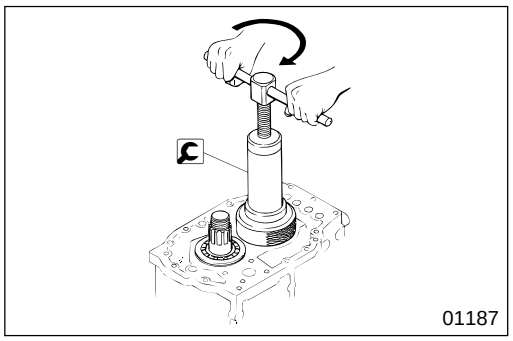
[Installation]
Press-fit front bearing retainer **3** into clutch housing assembly **18** using oil seal front guide.

CAUTION

Be careful when installing front bearing retainer 3, that you do not damage oil seal 2 installed on the front bearing retainer.

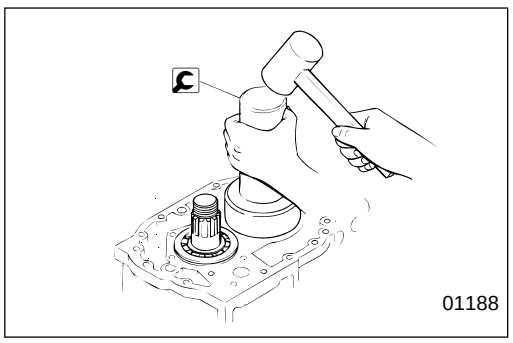


6 **7** **Removal and installation of snap ring**

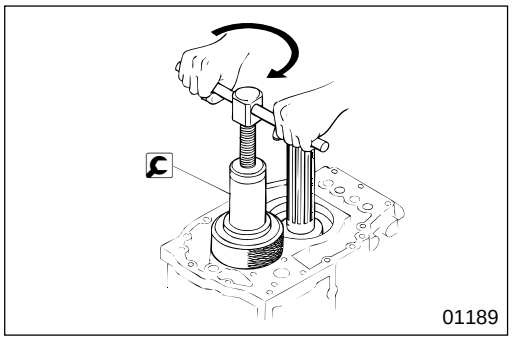


8 **Mainshaft rear bearing**

[Removal]

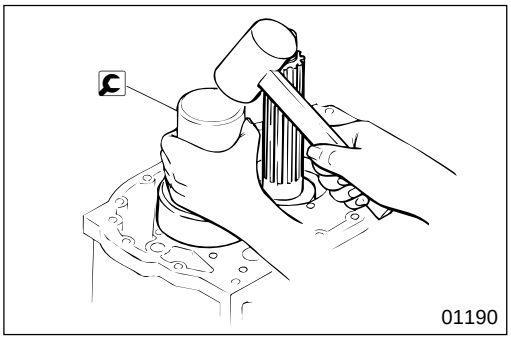


[Installation]

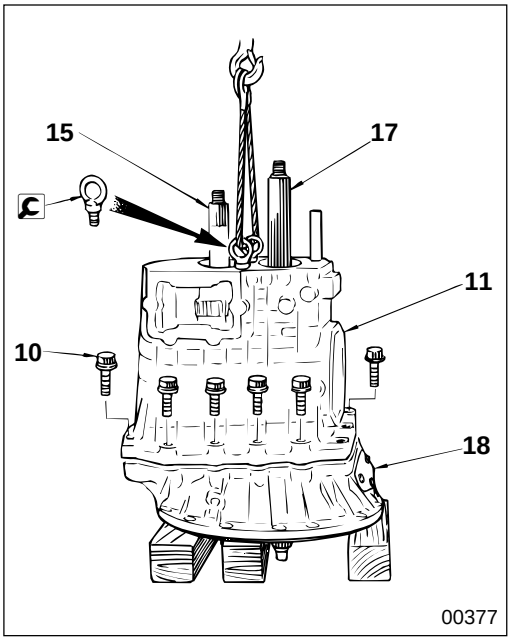


9 **Countershaft rear bearing**

[Removal]



[Installation]



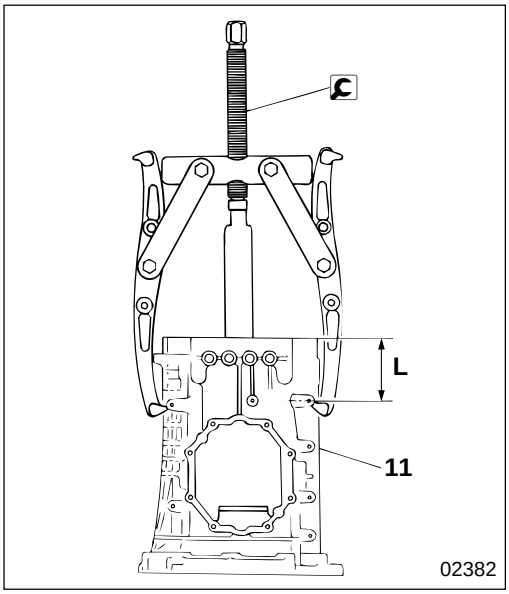
11 Removal and installation of transmission case

[Removal]

● **Remove transmission case 11.**

Method 1

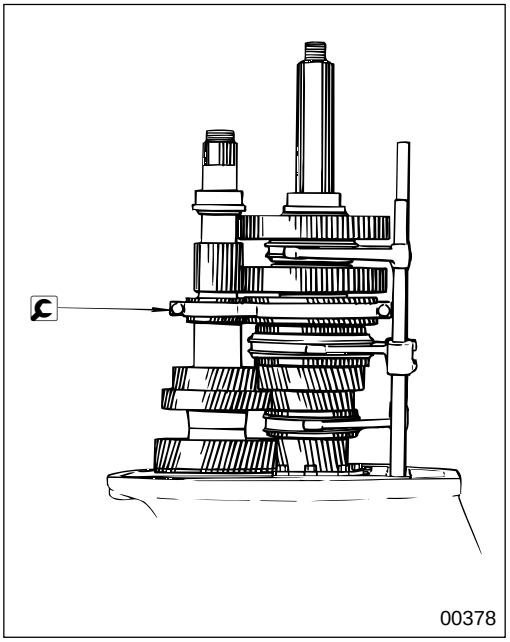
- When lifting up with a crane, install eye bolts on transmission case **11** and pass a steel sling through them.
- After removing bolts **10**, lift transmission case **11** up with a crane and keep hitting the rear ends of clutch housing assembly **18**, mainshaft assembly **17** and countershaft assembly **15**. Use a plastic-headed or copper-headed mallet to remove the transmission case.



Method 2

- A gear puller can be used instead of a crane.
  Puller installation position

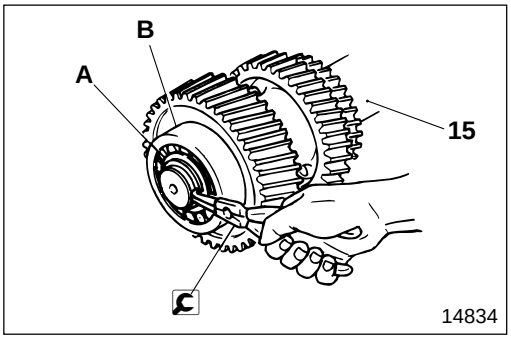
Model	Dimension of L mm {in.}
M060S6 O/D	146 {5.75}
M060S6 D/D	36 {1.42}
M070S6	93 {3.66}



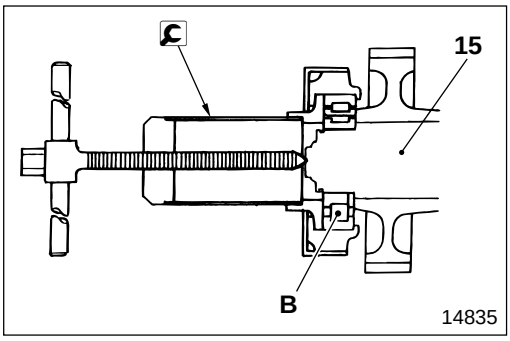
- After removing transmission case **11**, fit the 2nd gear unit < O/D > or 3rd gear unit < D/D > using steel lifting band to ensure safety.

CAUTION

Be sure to tighten steel lifting band adequately enough to prevent it from coming undone, but not excessively, because excessive tightening would damage the gears, etc.



- Remove snap ring **A** from countershaft assembly **15**.
  B : Countershaft front bearing

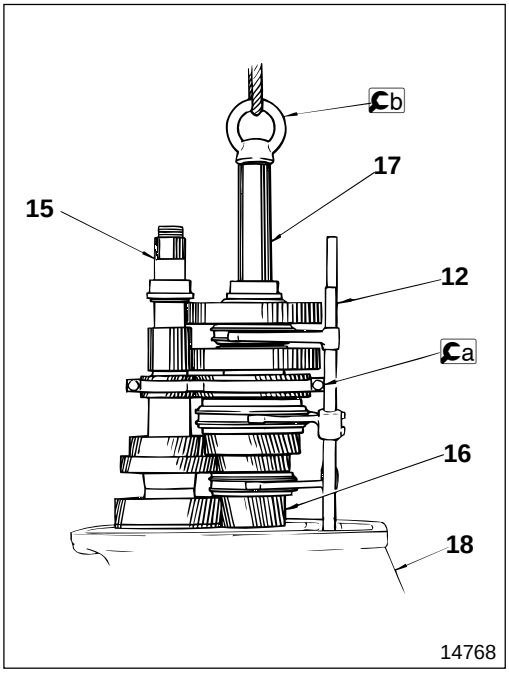


- Remove countershaft bearing **B** from countershaft assembly **15**.

[Installation]
Follow the removal sequence in reverse.

CAUTION

Be careful not to damage mainshaft assembly 17, or rear bearings 8, 9 of countershaft assembly 15 during installation.



12 **15** **to** **17** **Shift rail and shift fork, countershaft assembly, drive pinion assembly, and mainshaft assembly**

[Removal]
Remove or install shift rail and shift fork **12**, countershaft assembly **15**, drive pinion assembly **16**, and mainshaft assembly **17** as a group.

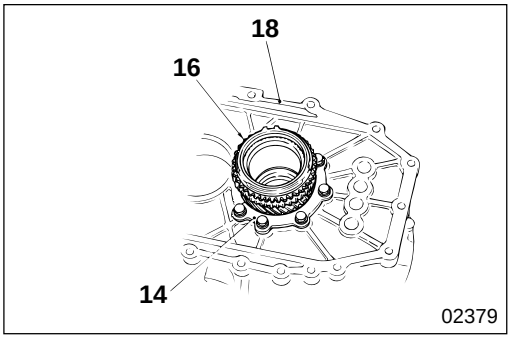
- Before lifting, after removing the case, install b eye nut at the end of mainshaft **17**, fitted with a steel lifting band.
- Fix shift rail and shift fork **12** to mainshaft assembly **17** with a rubber band.
- Fix a piece of wood to clutch housing assembly **18**, and use a crane to lift the clutch housing together with drive pinion assembly **16** up, at the same time hitting them with a plastic-headed mallet to remove them.

CAUTION

- **Be sure to tighten a steel lifting band adequately enough to prevent it from coming undone, but not excessively, because excessive tightening would damage the gears, etc.**
- **Make sure, when lifting mainshaft assembly 17 or other parts, that you support drive pinion assembly 16 with your hand in order to prevent it from falling when the mainshaft assembly and countershaft assembly 15 come apart.**

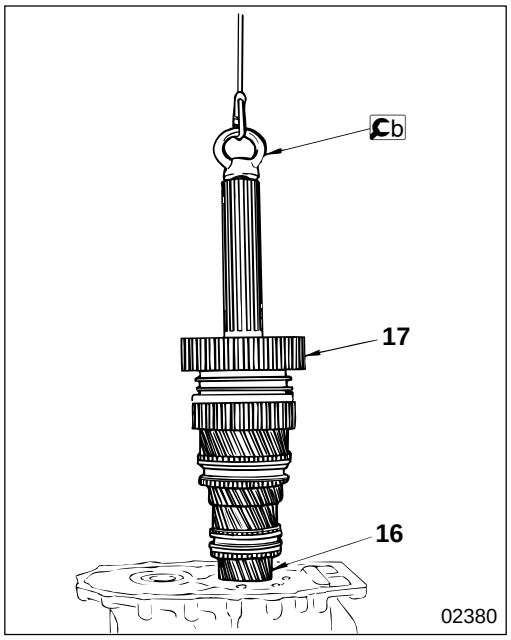
[Installation]
Method 1

- Follow the removal sequence in reverse.



Method 2

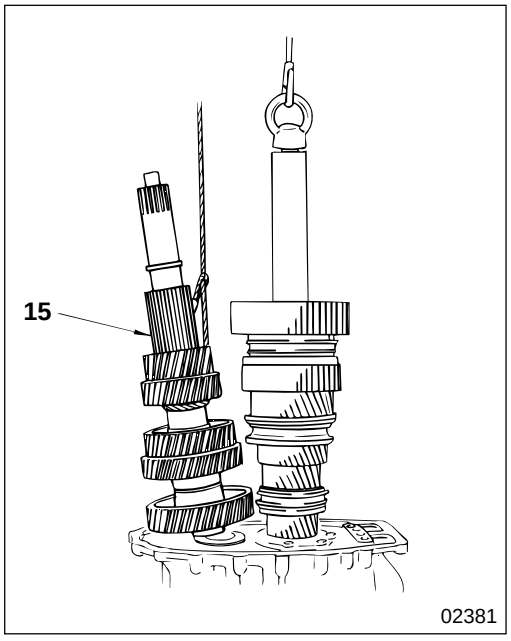
- After installing drive pinion assembly **16** in clutch housing assembly **18**, install drive pinion bearing retainer **14**.



- Install b eye nut at the end of mainshaft assembly **17**.
- Lift mainshaft assembly **17** up using a crane and install the mainshaft assembly on drive pinion assembly **16**.

CAUTION

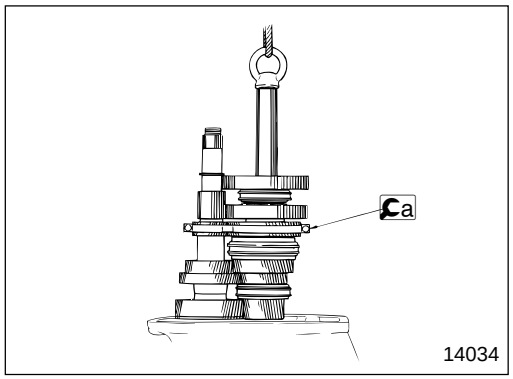
To prevent mainshaft assembly 17 from falling, support it using a crane.



- Install countershaft assembly **15** in clutch housing assembly **18**.

CAUTION

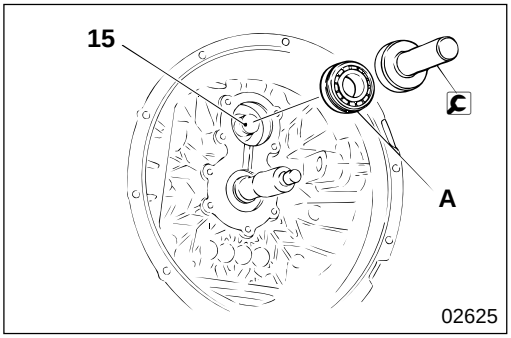
If you use this method of installation, first remove the countershaft front bearing. 🕮 P22A-84



- Fit the 2nd gear unit using a steel lifting band to ensure safety.

CAUTION

Be sure to tighten a steel lifting band adequately enough to prevent it from coming undone, but not excessively, because excessive tightening would damage the gears, etc.



- Install shift rail and shift fork **12** and transmission case **11** in clutch housing assembly **18**.
- Place cluch housing assembly **18** horizontally so that countershaft assembly **15** is uppermost.
- Install the countershaft front bearing **A** into clutch housing assembly **18** using countershaft bearing installer.

CAUTION

Be sure to install the snap ring of the countershaft front bearing.

◆ Service procedure

● **Work before disassembly**

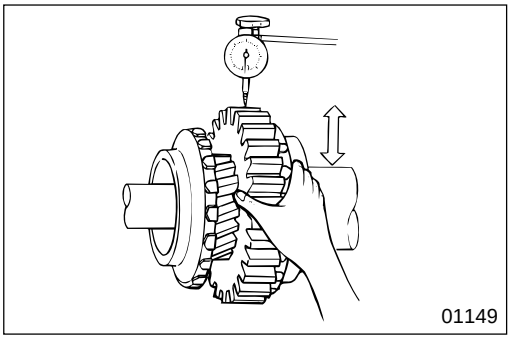
[Inspection]

(1) End play of gears

A : Reverse gear
B : 2nd gear
C : 3rd gear
D : 4th gear
E : 1st gear

If the measured value is higher than the limit, replace the faulty parts.

Also inspect this item after assembly and make sure that the measured value is within the limit.

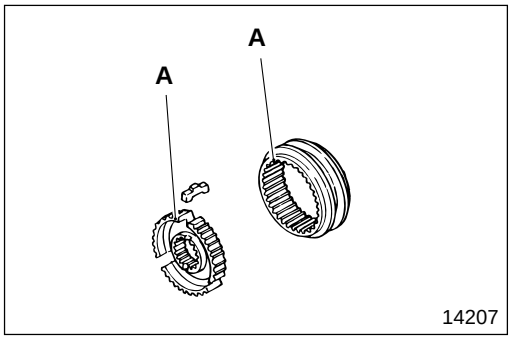


(2) Play of gears in diameter direction

If the measured value is higher than the limit, replace the faulty parts. Also inspect this item after assembly and make sure that the measured value is within the limit.

CAUTION⚠

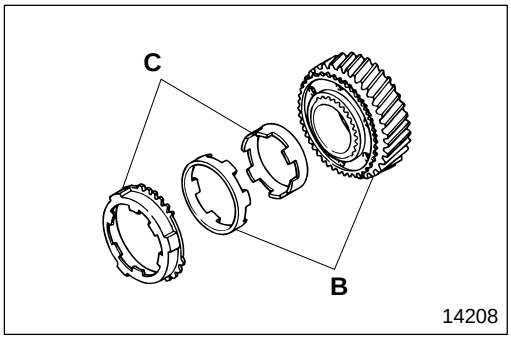
Be sure when you replace the two needle bearings of a gear, that both needle bearings are from the same color package.



[Alignment marks]

(1) Synchronizer sleeve and synchronizer hub

Before disassembling the synchronizer sleeve and the synchronizer hub, put alignment marks **A** on the places where the shifting keys are installed. When reusing parts, align the alignment marks to assemble.



(2) Ring, cone and gear assembly of double cone synchronizer

Before disassembling synchronizer center cone and gear assembly (**B**), and synchronizer center ring and synchronizer outer ring (**C**), put alignment marks on them. When reusing parts, align the alignment marks to assemble.

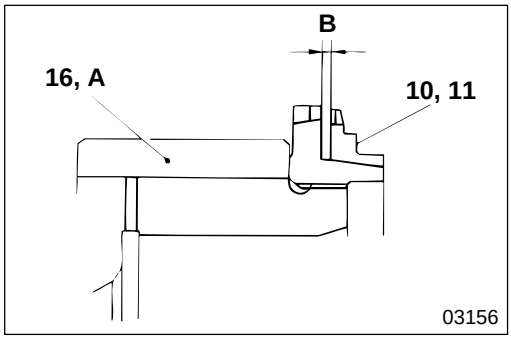
[Inspection]

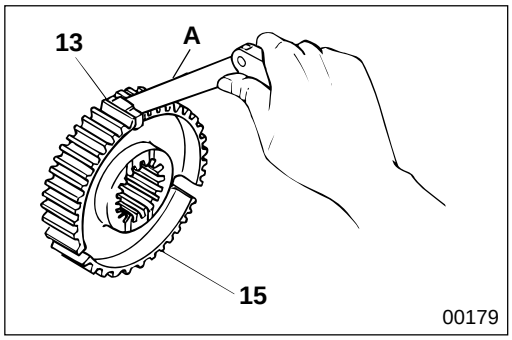
(1) Clearance between synchronizer ring 10 and shifting key 13

If the measured value is higher than the limit, replace the faulty parts.



(2) Clearance between synchronizer ring 10, 11 and drive pinion or 4th gear 16.

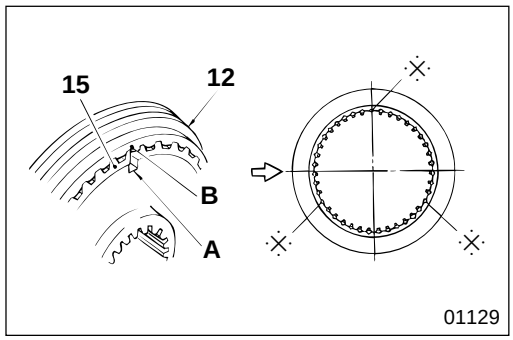
- Measure clearance **B** between synchronizer ring **10, 11** and the gear cone of drive pinon **A** or 4th gear **16**.
- When measuring this value, press synchronizer ring **10, 11** evenly, and measure all around the circumference.
- If the measured value is lower than the limit, replace the faulty parts.



(3) Clearance between shifting key 13 and synchronizer hub 15

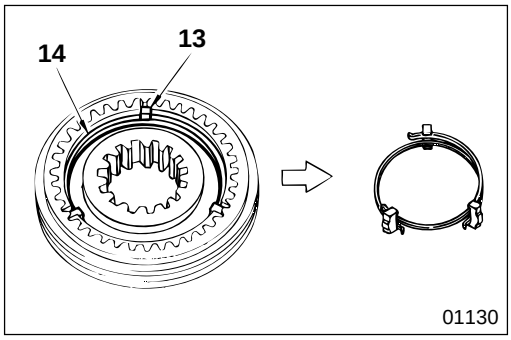
If the measured value is higher than the limit, replace the faulty parts.

A : Feeler gauge

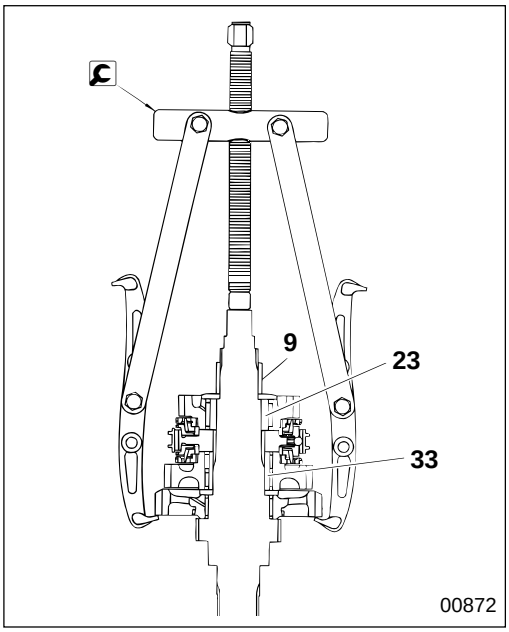


[Installation]

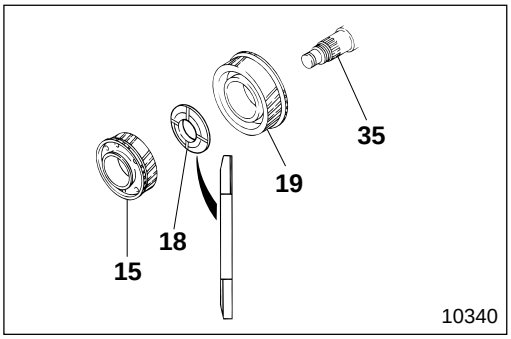
- Align the three keyways **A** of synchronizer hub **15** with the three stub teeth **B** (illustrated by ·⁜· mark) of synchronizer sleeve **12** to install the synchronizer hub.
- To reassemble synchronizer hub **15** and synchronizer sleeve **12**, align the alignment marks made during diassembly.



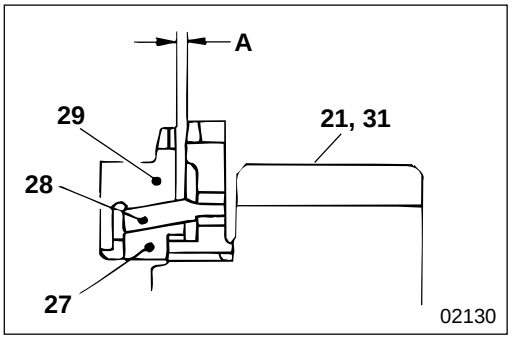
- Insert shifting key **13** into the keyway.
- Install shifting key spring **14** so that its opening is offset from the one of the shifting key.
- Make sure that the openings of shifting key springs do not align with each other.



19 23 33 Removal of 4th, 3rd, 2nd gear bearing sleeves



19 Installation of 3rd and 4th gear thrust washer



21 29 31 Clearance between synchronizer outer ring and 3rd gear assembly or 2nd gear assembly

- Measure clearance **A** between synchronizer outer ring **29** and the cone of 3rd gear assembly **21** or 2nd gear assembly **31**.
- When measuring this value, press synchronizer inner ring **27**, synchronizer outer ring **29** and synchronizer center ring **28** evenly and measure all around the circumference.
- If the measured value is higher than the limit, replace the faulty parts.

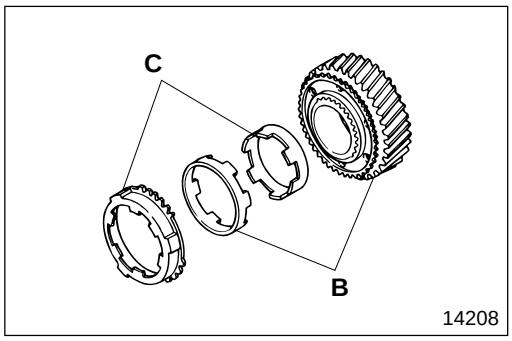
[Alignment marks]

(1) Synchronizer sleeve and synchronizer hub

Before disassembling the synchronizer sleeve and the synchronizer hub, put alignment marks **A** on the places where the shifting keys are installed. When reusing parts, align the alignment marks to assemble.



(2) Ring, cone and gear assembly of double cone synchronizer

Before disassembling synchronizer center cone and gear assembly (**B**), and synchronizer center ring and synchronizer outer ring (**C**), put alignment marks on them. When reusing parts, align the alignment marks to assemble.

◆ Service procedure

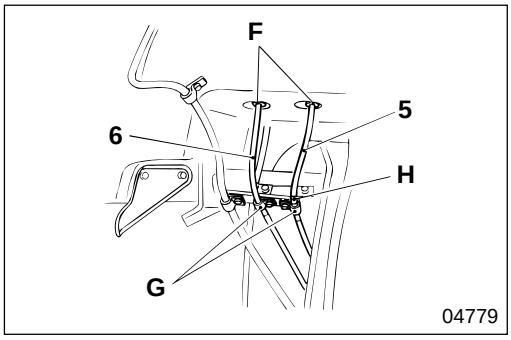
5 **6** **Installation of shift cable and selector cable**

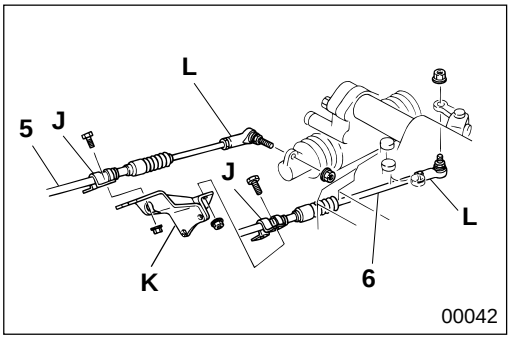
CAUTION⚠

- **Make sure the identification marks on the cable, ball joint L, and rubber damper M point in the right direction when you install the cables. Installing the cables with the identification marks in the wrong direction can remarkably reduce the durability of the cables.**
- **Install casing cap A lengthwise.**
- **Make sure the radius of the bend is 200 mm {7.87 in.} or more.**
- **Make sure the cable operates smoothly.**
- **Install the clamp vertically against the cable. (Figure B)**
- **Do not twist clamps C at both ends of the boot. Make sure that white line D on the boot is straight. (Figure E)**



- Insert shift cable **5** and selector cable **6** under the cab floor and clamp them in the correct place by identifying identification mark **H** on the shift cable. (The selector cable has no identification mark.)
  F : Grommet
  G : Clip

< With Power Shift >

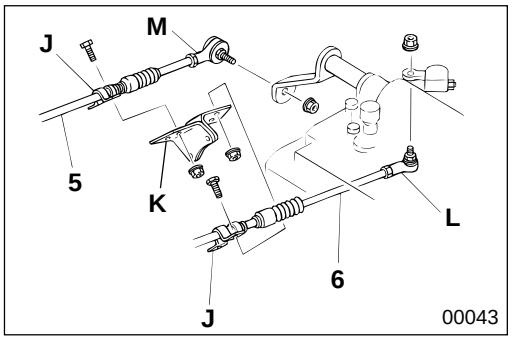


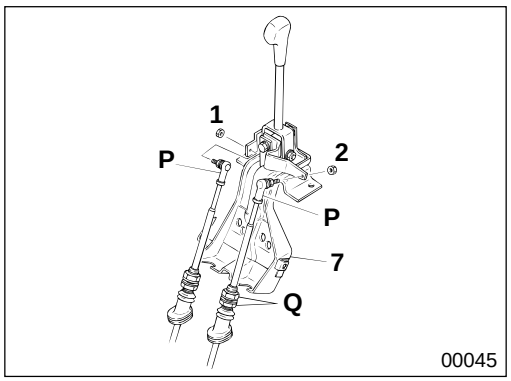
- Install cable clip **J** to bracket **K** temporarily and connect ball joint **L** or rubber damper **M** to the shift lever or selector lever.
- Arrange the cable so that it not twisted, then tighten clip **J** permanently.

CAUTION⚠

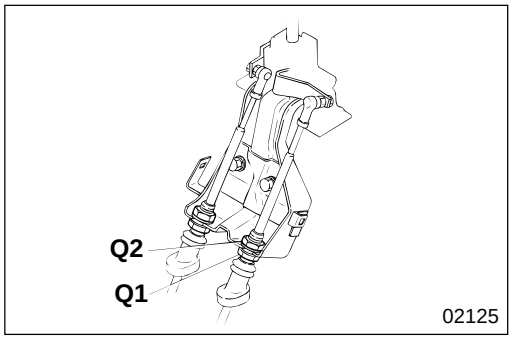
Make sure that ball joint L and rubber dumper M face the correct direction.

< Without Power Shift >





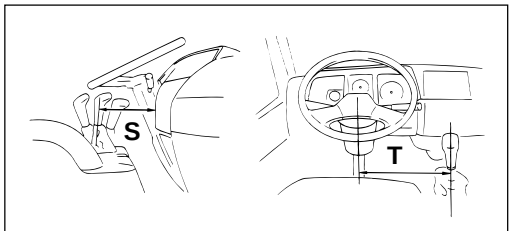
- Tilt the cab down.
- Install the cable on set board assembly **7** temporarily and connect ball joint **P** to shift lever **A** and selector lever **B**.
- Arrange the cable so that it is not twisted, then tighten lock nuts **Q** permanently.

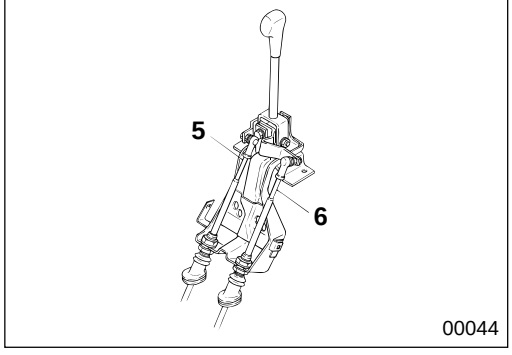


CAUTION⚠

- **Make sure that ball joint L faces the correct direction.**
- **When installing the lock nut, tighten lower nut Q1. Do not move nut Q2.**

- Make sure when you operate the gear shift lever that it shifts smoothly and selects each position.





- If the gear shift lever leans to the front or rear, or to the left or right, excessively, adjust the length of the cable.
- When positioning the gear shift lever, use the distance from the center of the steering wheel or from the instrument panel as the reference distance.

13 Drive pinion

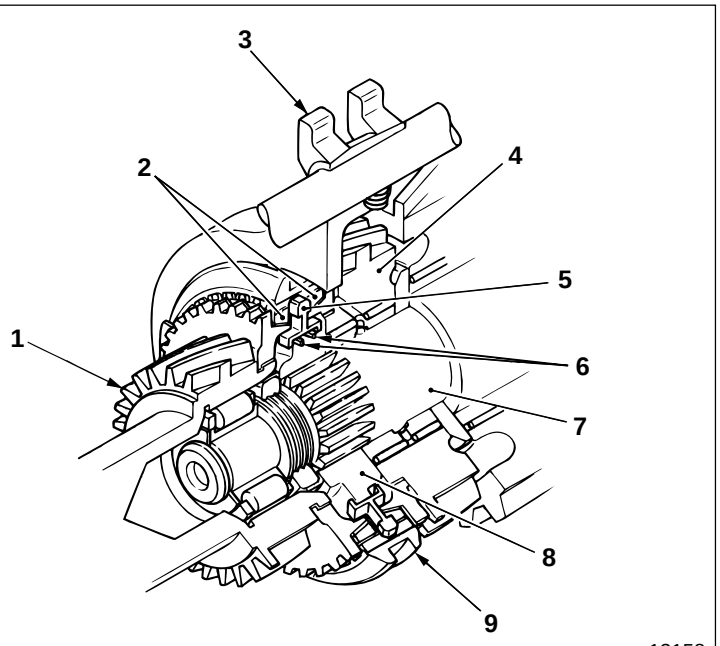
The transmission changes revolution and torque produced by the engine into those that match the vehicle's power requirement (driving force). Revolution and torque are increased or decreased by making a selection from several sets of engaged gears.
The transmission can also change the direction of rotation of the engine output. As the engine always turns in one direction, this allows the vehicle to be reversed. The rotation of the drive pinion is transmitted to the countershaft by the constant mesh gear, and a change in speed is made as the gears, or gear sections, on this countershaft engage those on the mainshaft. In 5th speed the drive pinion rotation is transmitted directly. This M8S2×5 transmission is a HIGH and LOW splitter type. The selector switch on the gearshift lever permits selection of ten forward speeds and two reverse gears by combining 2-speed splitter gears and 5-speed transmission gears.
The power shift lightens the shift operating force of the transmission.

Synchromesh Mechanism

This vehicle has two synchromesh mechanisms, a single cone type, and a double cone type, and uses the key system. The single or double cone type is used depending on the gear positions as shown below:

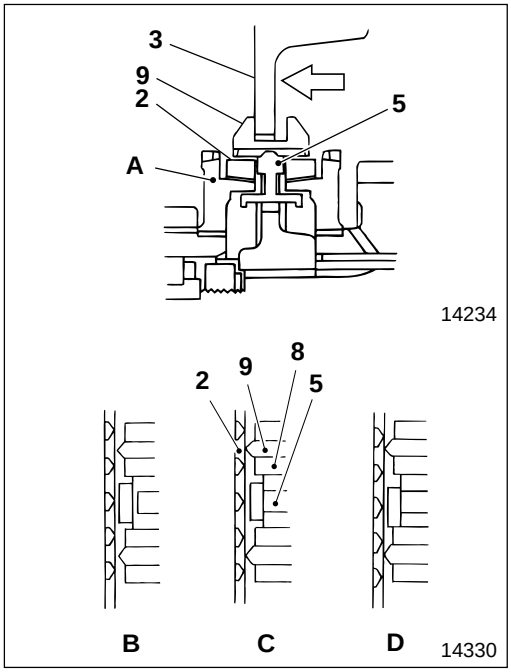
Synchronizer type	Parts used
Single cone type	4th and 5th
Double cone type	2nd and 3rd

Single Cone Type

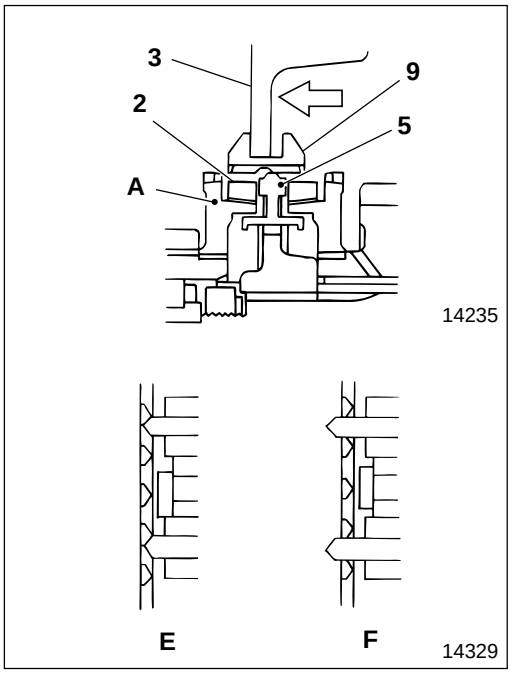


1 Drive pinion
2 Synchronizer ring
3 4th and 5th shift fork
4 4th gear
5 Shifting key
6 Shifting key spring
7 Mainshaft
8 Synchronizer hub
9 Synchronizer sleeve

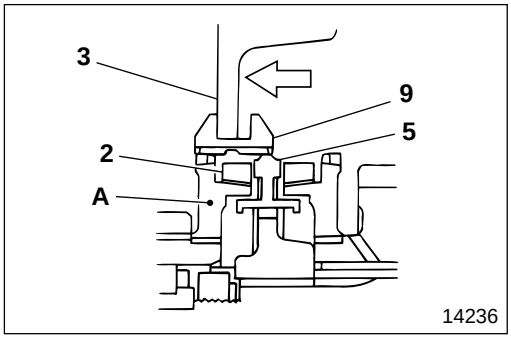
- The inside of synchronizer hub **8** engages the spline of mainshaft **7** and rotates with it. The outside of the synchronizer hub has a spline that engages synchronizer sleeve **9** and three keyways.
- Shifting keys **5** are inserted into these keyways. When the gear shift is in neutral, a protrusion in the center of each shifting key engages a groove inside the synchronizer sleeve and the shifting keys are pressed against the inside of the synchronizer sleeve by shifting key springs **6**.
- Synchronizer rings **2** are inserted into drive pinions **1** in the front and rear of synchronizer hub **8**, and the taper cone of 4th gear **4**.
- Synchronizer rings **2** rotate relative to synchronizer sleeve **9** by the amount of play of the keyways.



- When the gear shift is in neutral (Figure **B**), moving shift fork **3** in the direction of the arrow as illustrated, moves synchronizer sleeve **9** slightly to the left. At the same time, shifting key **5**, the central protrusion of which engages the synchronizer sleeve, moves to the left and presses synchronizer rings **2** against taper cone **A** of drive pinion **1**. (Figure **C**)
- When the taper surfaces of synchronizer rings **2** make contact with the taper cone of the drive pinion, the taper surfaces of the synchronizer rings act as cone clutches. This frictional torque rotates the synchronizer rings in the rotating direction of the drive pinion by the amount of play between synchronizer hub **8** and the synchronizer rings. The spline chamfers of the synchronizer rings and the spline chamfer of synchronizer sleeve **9** are offset from each other. (Figure **D**)
- The disengagement direction of synchronizer rings **2** is defined by the speed of rotation of the synchronizer—sleeve **9**, and the synchronized—drive pinion **1**. When increasing the vehicle speed by shifting up, disengagement is made in the opposite direction to rotation, and when decreasing the vehicle speed by shifting down, disengagement is made in the rotating direction.

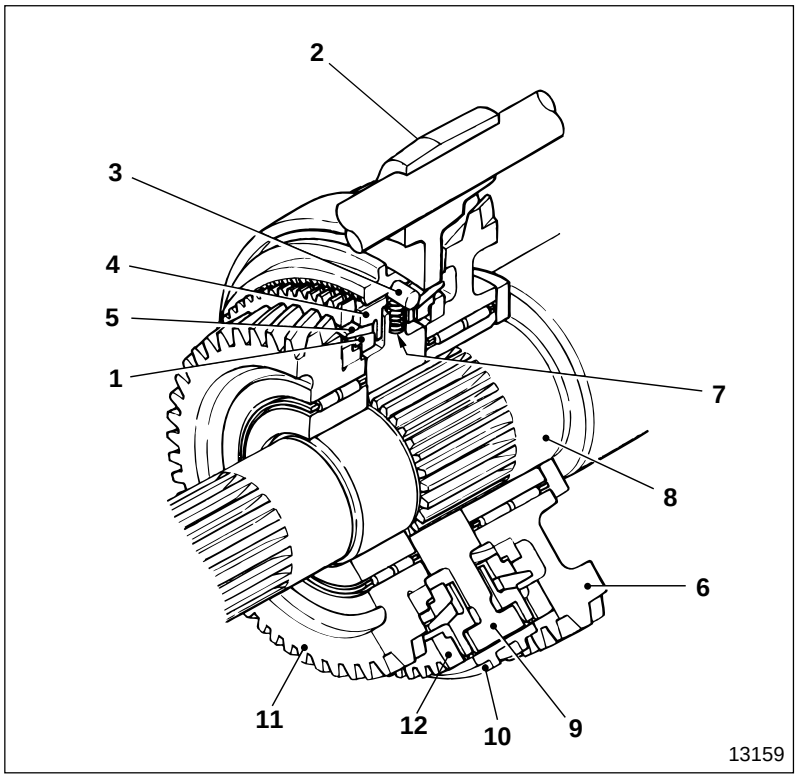


- When synchronizer sleeve **9** moves further to the left, synchronizer rings **2** prevent shifting key **5** from moving, and the synchronizer sleeve disengages from the protrusion of the shifting key.
- Since synchronizer rings **2** remain disengaged, the spline chamfer of synchronizer sleeve **9** presses the spline chamfers of the synchronizer rings, which in turn press the synchronizer rings against taper cone **A** of drive pinion **1**.
- As the frictional torque increases on the taper surfaces, the relative speed of the synchronizer and the synchronized gradually decreases.
  E : In synchronization
  F : After synchronization



- When synchronizer sleeve **9** and drive pinion **1** rotate at the same speed, synchronizer rings **2** no longer prevent the synchronizer sleeve from moving, and the synchronizer sleeve moves further to the left and smoothly engages the spline of taper cone **A** of drive pinion **1**, transmitting the driving force.

Double Cone Type

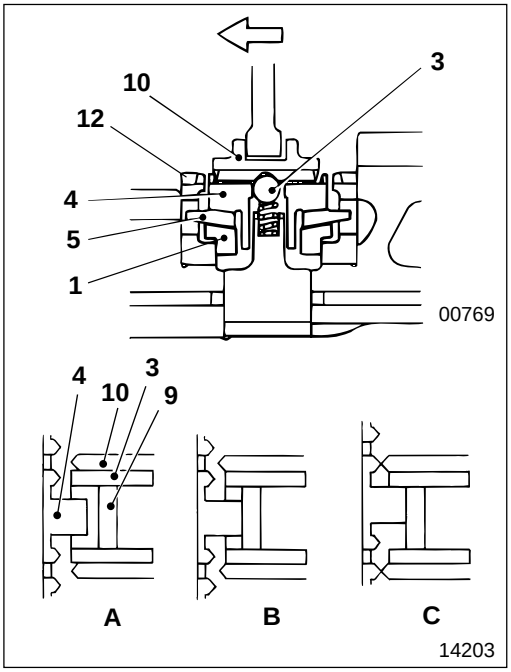


1 Synchronizer inner ring
2 2nd and 3rd shift fork
3 Shifting key
4 Synchronizer outer ring
5 Synchronizer center cone
6 2nd gear
7 Shifting key spring
8 Mainshaft
9 Synchronizer hub
10 Synchronizer sleeve
11 3rd gear
12 Dog clutch

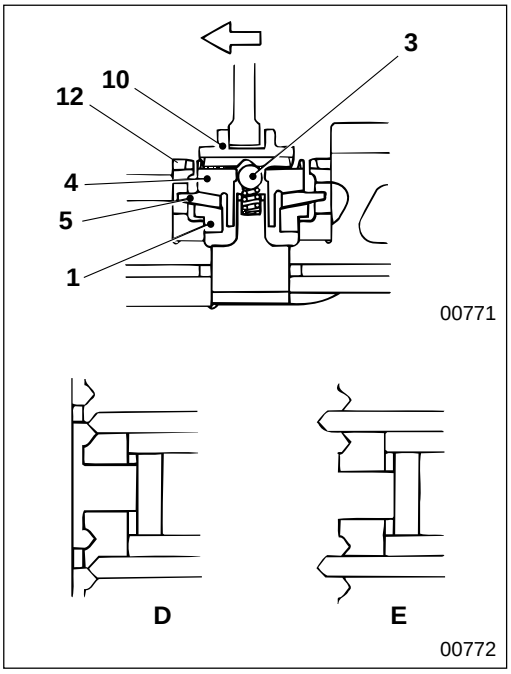
The synchromesh structure and operation of the double cone type are basically the same as for the single cone type.

- Synchronizer center cone **5** is a taper cone independent of 2nd gear **6** and 3rd gear **11**, (both the inside and outside surfaces are tapered). The synchronizer center cone is between synchronizer inner ring **1** and synchronizer outer ring **4** to increase the synchronization capacity.
- Six protrusions on the outside of center cone **5** fit into corresponding gear holes, in the same manner as the taper cone of the single cone type. The center cone and the gear are installed as if integrated.

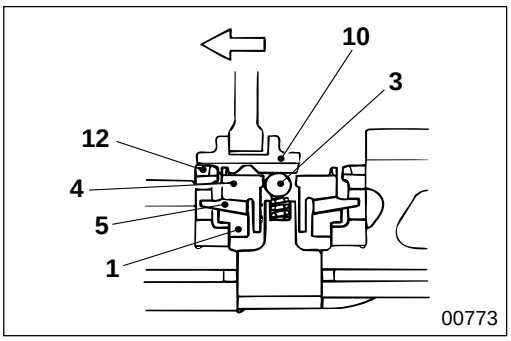
  Shifting key **3** is a cylinder installed so that the lengthwise direction of the cylinder is at right angles to the diameter direction of synchronizer hub **9**. Shifting key spring **7** is a coil spring inserted in a hole in the synchronizer hub, this spring presses the shifting key against the inside of synchronizer sleeve **10**.



- When the gear shift is in neutral (Figure **A**), moving shift fork **2** in the direction of the arrow as illustrated, moves synchronizer sleeve **10** slightly to the left. At the same time, shifting key **3**, the central protrusion of which engages the synchronizer sleeve, moves to the left and presses synchronizer outer ring **4** against synchronizer center cone **5**. (Figure **B**)
- When the taper surface of synchronizer outer ring **4** makes contact with the taper cone of synchronizer center cone **5**, the taper surface of the synchronizer outer ring acts as a cone clutch. This frictional torque rotates the synchronizer outer ring in the rotating direction of 3rd gear **11** by the amount of play between the synchronizer outer ring and synchronizer hub **9**. The spline chamfer of the synchronizer outer ring and the spline chamfer of synchronizer sleeve **10** are offset from each other. (Figure **C**)
- The disengagement direction of synchronizer outer ring **4** is defined by the speed of rotation of the synchronizer—the sleeve, and the synchronized—3rd gear **11**. When increasing the vehicle speed by shifting up, disengagement is made in the opposite direction to rotation, and when decreasing the vehicle speed by shifting down, disengagement is made in the rotating direction.



- When synchronizer sleeve **10** moves further to the left, synchronizer outer ring **4** prevents shifting key **3** from moving, and the synchronizer sleeve disengages from the protrusion of the shifting key.
- Since synchronizer outer ring **4** remains disengaged, the spline chamfer of synchronizer sleeve **10** presses the spline chamfer of the synchronizer outer ring, which in turn presses the synchronizer outer ring against the taper cone of synchronizer center cone **5**, and the frictional torque acts on the taper surface.
- As the frictional torque increases on the taper surface of synchronizer inner ring **1**, the relative speed of the synchronizer and the synchronized gradually decreases. The frictional torque acts on both sides of the synchronizer center cone. The double cone type has greater capacity for synchronization than the single cone type.
  D : In synchronization
  E : After synchronization



- When synchronizer sleeve **10** and 3rd gear **11** rotate at the same speed, synchronizer outer ring **4** no longer prevents the synchronizer sleeve from moving and the synchronizer sleeve moves further to the left and smoothly engages the spline of dog clutch **12** of the 3rd gear, transmitting the driving force.

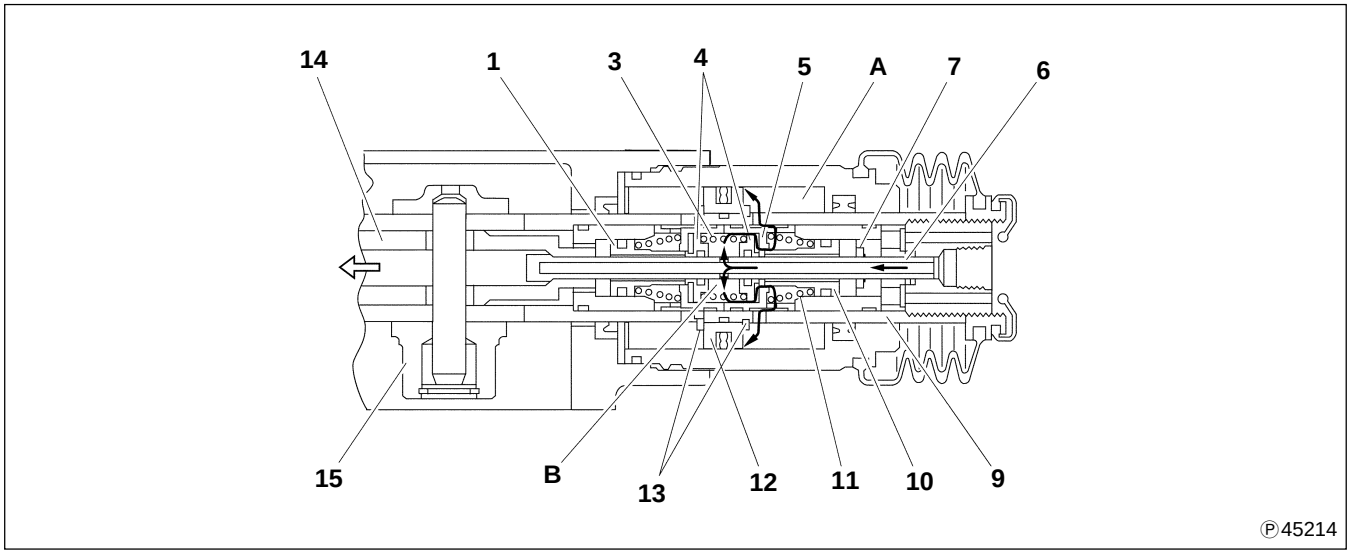
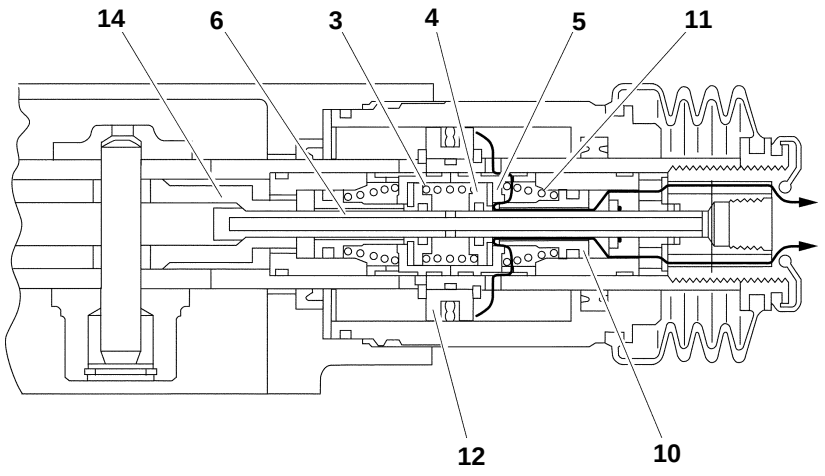
6 Pipe
7 Plate
8 Retaining ring
9 Shifter rod
10 Valve lifter
11 No. 3 spring
12 Piston
13 Retaining ring
14 Actuating rod
15 Striker

A : Secondary chamber
B : Primary chamber



When activated

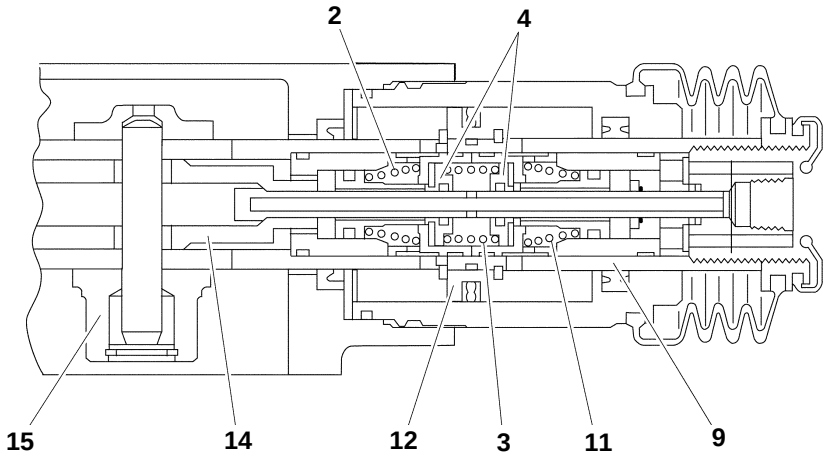
- When actuating rod **14** is moved in the direction of the arrow shown, a relative displacement occurs between shifter rod **9** and the actuating rod.
  This causes valve lifter **10** to compress no. 3 spring **11**, pushing valve seal **4**. The force of the valve lifter overcomes the forces of the compressed air and no. 2 spring **3**, separating the valve seal from the valve seat **5**. As a result, the compressed air being supplied to primary chamber **B** is allowed to go through the gap between the valve seat and the valve seal into seconday chamber **A**. The compressed air then passes through the hole in the valve seat and flows along the groove on its periphery and through the vent hole in the shifter rod into the cylinder, thus applying pressure to piston **12** to generate output power.
- The output power generated at piston **12** is transmitted via retaining ring **13** to shifter rod **9**, giving impetus to striker **15** secured to the shifter rod. This in turn actuates the shift fork on the transmission side, effecting gearshifting. This is the flow of operation from the start to end of gearshifting.
- When the actuating direction is as indicated by the arrow in fig., the input from gearshift lever is transmitted from actuating rod **14** to the valve lifter via plate **7** that is secured on pipe **6** by retaining ring **8**. When the actuating direction is opposite, the operation is exactly the same, except that the end face of the actuating rod directly pushes valve lifter **1**.



Ⓟ45215

When released

- When the input is released as gearshifting is completed, actuating rod **14** is returned to the original position, that is, the central positionof the valve, by the reaction forces of compressed air from valve lifter **10** and valve springs **3** and **11**. As the valve lifter is pushed back, valve seal **4** seats snugly on valve seat **5**, cutting off the supply of compressed air from the primary chamber to secondary chamber. When the input rod is further returned, there is a clearance produced between valve lifter **10** and valve seal.
- This releases the compressed air in the secondary chamber (inside the cylinder) to the atmosphere through the clearance between valve lifter **10** and pipe **6**. As a result, there is no pressure difference between the two chambers located before and behind piston **12**, zeroing the output.

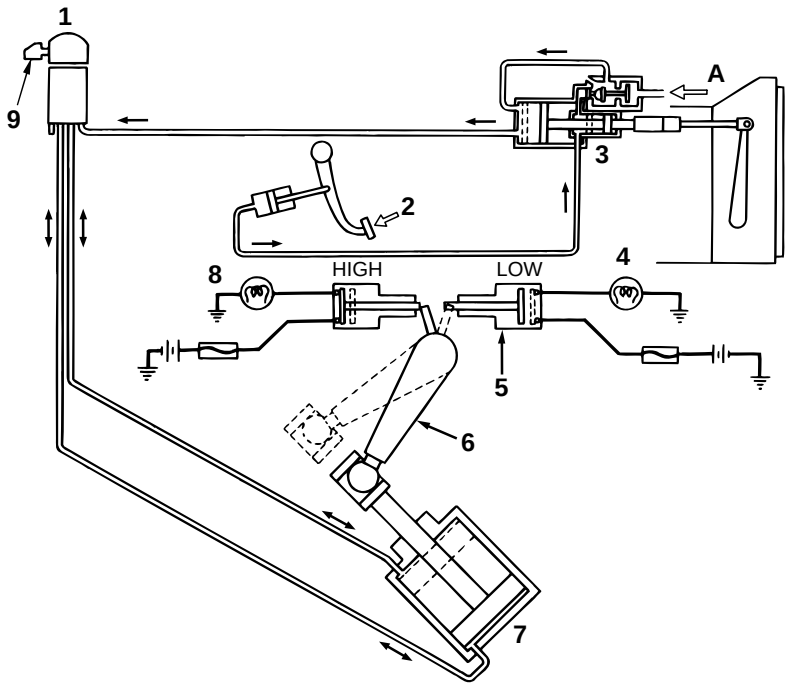


Ⓟ45216

When not activated (when no boost is given)

- To actuate the power shift, that is, to open the valve and send compressed air to the output chamber, it is necessary to produce a relative displacement in actuating rod **14** on the input shaft end and shifter rod **9** on the output shaft end.
- When an operating force is applied from the gearshift lever to actuating rod **14** and if the resistance on the transmission end is smaller than the sum of the drag produced as a result of relative changes in the input and output sides (that is, the reaction forces of no. 1 through 3 springs **2**, **3**, **11**; pressure applied to valve seal **4**; and sliding resistance of each part), the mechanism from the actuation rod to striker **15** moves as an integral unit and no relative displacement is produced. The valve is therefore not opened and piston **12** moves in the cylinder to effect gearshifting with no power boost applied.

Splitter Control



1 Air control valve
2 Clutch pedal
3 Clutch booster
4 LOW indicator lamp
5 Interlock switch
6 Splitter shift lever
7 Power cylinder
8 HIGH indicator lamp
9 Knob

A : From air tank

- The splitter control allows change over between HIGH and LOW by the operation of power cylinder **7** installed on the splitter, using air pressure taken from the clutch booster.
- Depressing clutch pedal **2** operates clutch booster **3**, supplying air to air control valve **1** installed on the gear shift lever by the driver's seat.
- To change over the supplied air from HIGH to LOW, move the knob of air control valve **1** to H or L respectively.
- This supplied air operates power cylinder **7** changing over the splitter between HIGH and LOW.
- Due to the restriction of the above mechanism, change over of the splitter is possible only when depressing clutch pedal **2**.
- Interlock switch **5** of the splitter upper assembly detects whether splitter shift lever **6** is in HIGH or LOW, and accordingly lights up HIGH indicator lamp **8** or LOW indicator lamp **4** within the meter cluster, to notify the driver.

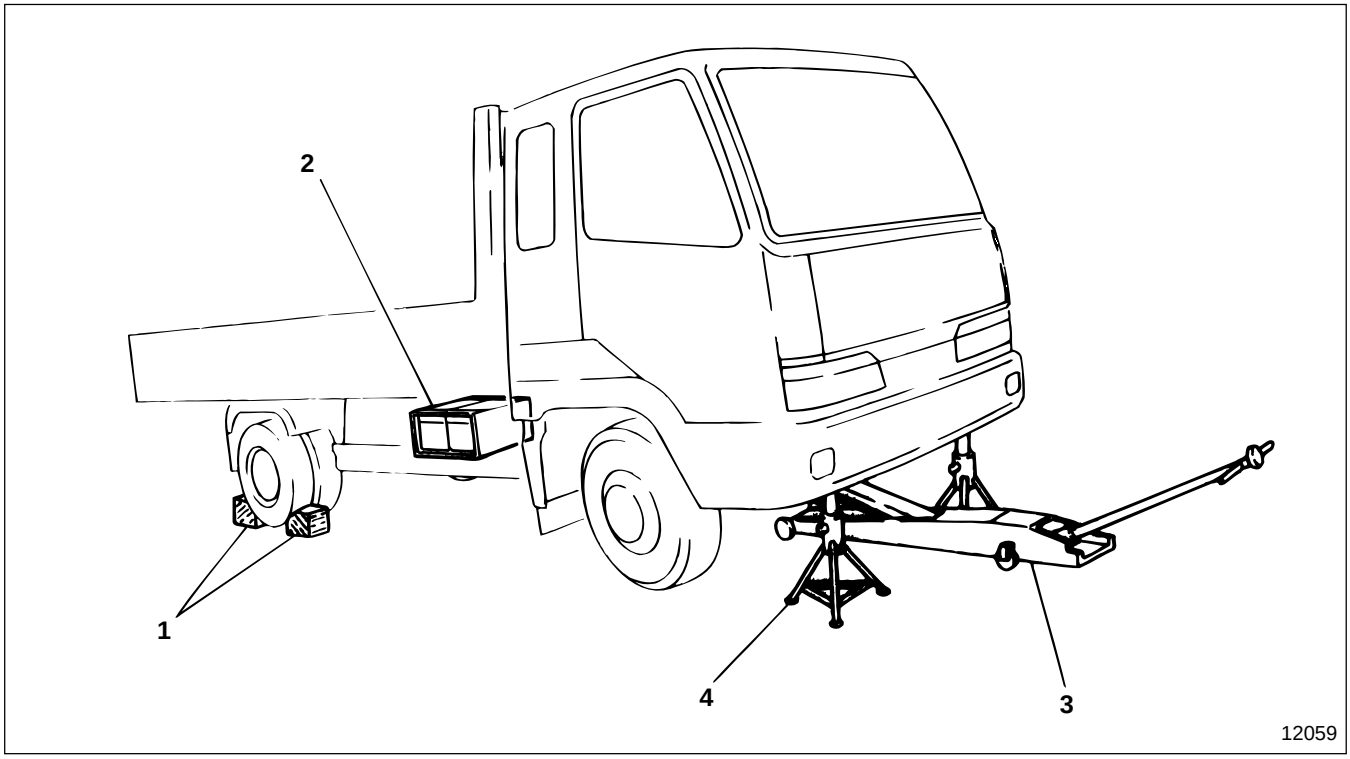
WORK BEFORE REMOVAL AND INSTALLATION OF TRANSMISSION ASSEMBLY



● **Work sequence before removal**

1 Place wheel chocks.
2 Disconnect negative battery cable. Gr 54
3 Jack up the front axle on a garage jack.
4 Support the front frame on rigid racks.

WARNING

- **You must chock the wheels securely so the vehicle does not move.**
- **Do not remove the chocks until the entire operation is completed.**
- **Supporting a vehicle on a garage jack only is extremely dangerous, so always support the frame on rigid racks.**
- **Leave the garage jack and rigid racks in place until the entire operation is completed. Never remove them during the operation.**

CAUTION

Keep the transmission in neutral throughout the operation.

● **Work sequence after installation**

Follow the work sequence before removal in reverse.

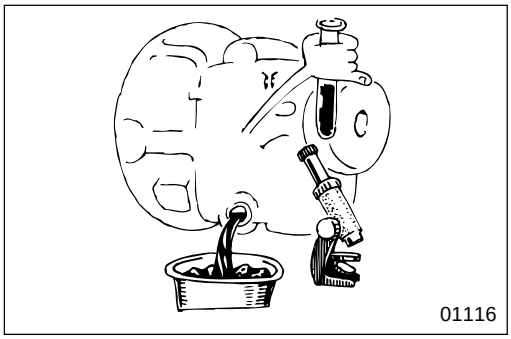
◆ Service procedure



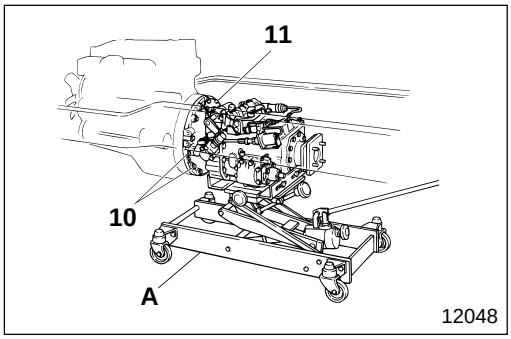
● Oil change

[Draining]

- When draining oil, check the quantity and quality of oil, especially for small pieces of metal and metal dust.
- Clean drain plug **9** before reinstalling it because it is magnetic.

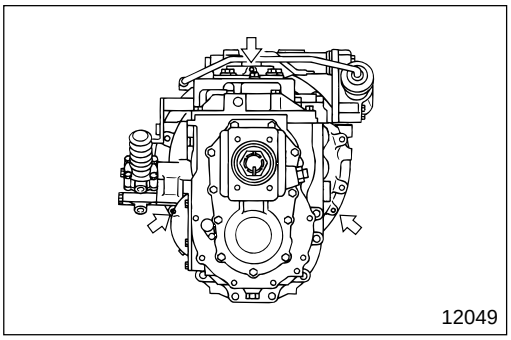
[Filling]

- Check that drain plug **9** is tightened at specified torque.
- Pour in gear oil until the oil overflows from the inspection hole.



10 Removal of transmission assembly mounting nut or bolt

- Support transmission assembly **11** on transmission jack **A**.
- Remove transmission assembly mounting nuts or bolts **10**.



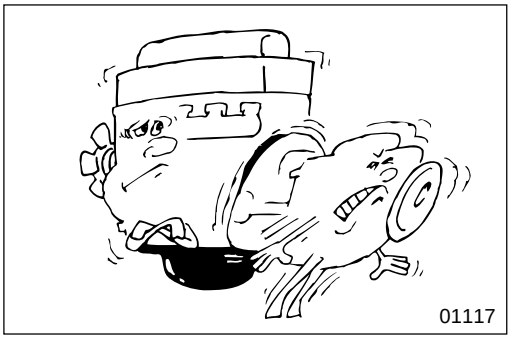
11 Transmission assembly

[Removal]

- Remove transmission assembly **11** from the engine using the screw holes (screw size : M10×1.5 mm) provided for disassembly.

CAUTION⚠

Make sure that you remove hoses and cables before starting service operations.

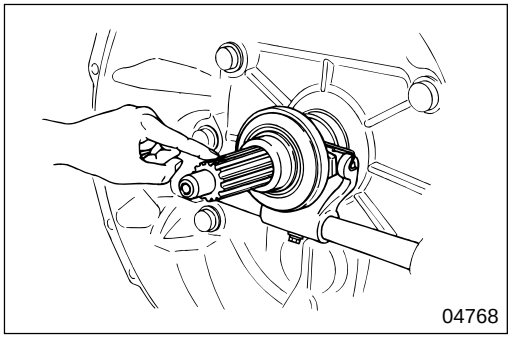


- Move transmission assembly **11** backward until the spline of the input shaft is detached from the clutch.

CAUTION⚠

Make sure that you pull transmission assembly 11 out in a straight line. If you seesaw the transmission assembly violently, you will damage the spline that connects the drive pinion and the clutch.

REMOVAL AND INSTALLATION OF TRANSMISSION ASSEMBLY

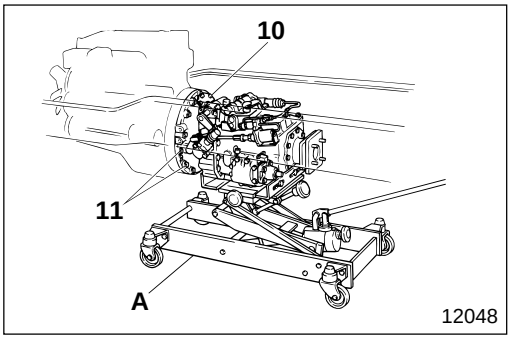


04768

[Installation]
- Check the spline of the input shaft for rust.
- If rust is found, remove it using a wire brush.
- Rub grease onto the clutch sliding surfaces of the input shaft using your hand.

CAUTION

Make sure that you apply only the necessary amount of grease because too much grease would drip and cause clutch slip.



12048

- Support transmission assembly **11** on transmission jack **A**.
- Insert transmission assembly **11** into the pilot bearing of the flywheel paying attention to the input shaft spline.
- Tighten transmission mounting nuts or bolts **10** at specified torque.

● Inspection before disassembly

(1) Apply 735 kPa {105 psi, 7.5 kgf/cm^2} of pressure to the power shift assembly from the connector, check the airtightness when not operating (valve in neutral), and when operating valve is pressed and pulled. If the measured value deviates from the standard value, replace the faulty parts.

Maintenance item	Standard value	
Airtightness when not operating	Decrease of pressure after 15 seconds	9.8 kPa {1.4 psi, 0.1 kgf/cm^2}
Airtightness when operating		49 kPa {7.1 psi, 0.5 kgf/cm^2}

(2) Measure the sliding resistance in the disengagement direction. If the measured value deviates from the standard value, replace the faulty parts, or grease them.

(2) Clearance in the diameter direction between input shaft, and splitter pinion assembly or needle bearing after assembling them on the shaft

If the measured values are higher than the limit, replace the faulty parts.

Also inspect this item after assembly and make sure that the measured value is within the limit.

CAUTION⚠

Be sure when you replace two needle bearings of a gear, that both needle bearings are from the same color package.

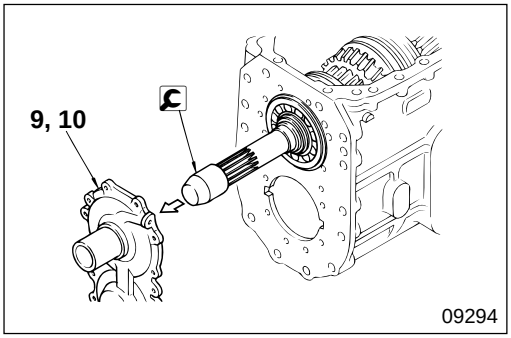
[Alignment marks]

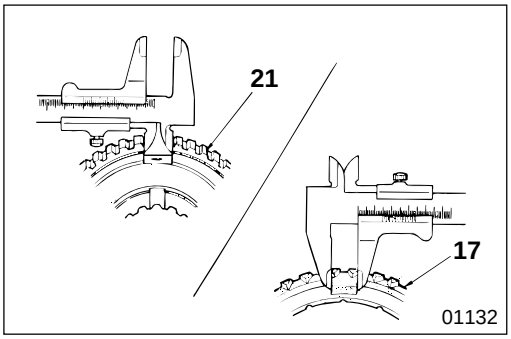
Synchronizer sleeve and synchronizer hub

Before disassembling the synchronizer sleeve and the synchronizer hub, put alignment marks **A** on the places where the shifting keys are installed. When reusing parts, align the alignment marks to assemble.



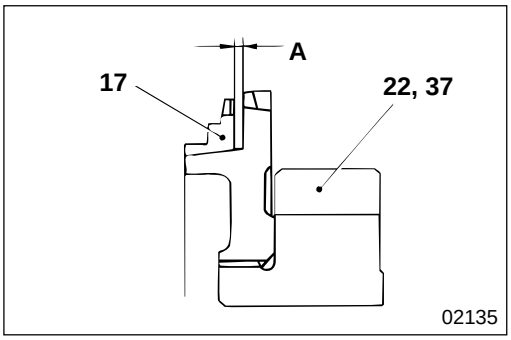
10 **Installation of bearing retainer**

When installing bearing retainer **10**, use oil seal front guide to avoid damage to oil seal **9**, which is installed on the bearing retainer.



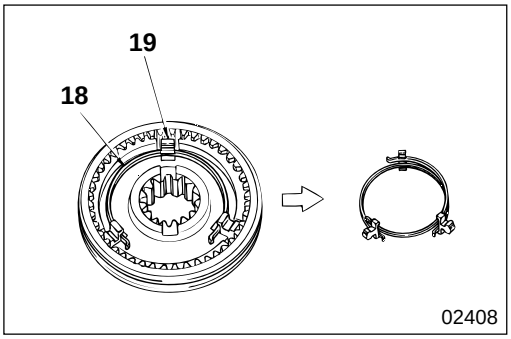
17 **21** **Clearance between synchronizer ring and synchronizer hub**

If the measured value is higher than the limit, replace the faulty parts.



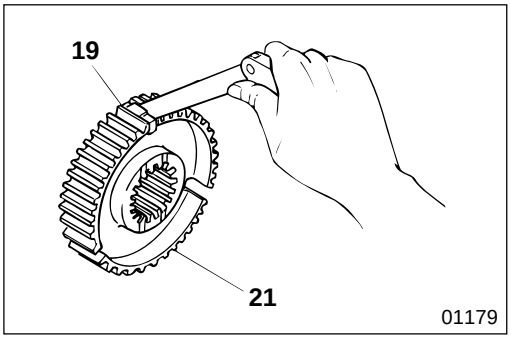
17 **22** **37** **Clearance between synchronizer ring, and splitter pinion or splitter synchronizer cone**

- Measure clearance **A** between synchronizer ring **17** and splitter pinion **22** or splitter synchronizer cone **37**.
- When measuring this value, press synchronizer ring **17** evenly and measure all around the circumference.
- If the measured value is lower than the limit, replace the faulty parts.



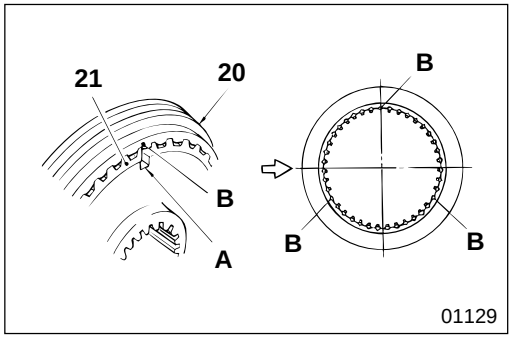
18 **Installation of shifting key spring**

- Insert shifting key **19** into the keyway.
- Install shifting key spring **18** so that its opening is offset from the one on the shifting key.
- Make sure that the opening of shifting key springs **18** do not align with each other.



19 **21** **Clearance between shifting key and synchronizer hub**

If the measured value is higher than the limit, replace the faulty parts.



20 **Installation of synchronizer sleeve**

- Align the three keyways **A** of synchronizer hub **21** with the three stub teeth **B** of synchronizer sleeve **20** to install the synchronizer hub.
- To reassemble synchronizer hub **21** and synchronizer sleeve **20**, align the alignment marks made during disassembly.

● Work before disassembly

[Inspection]

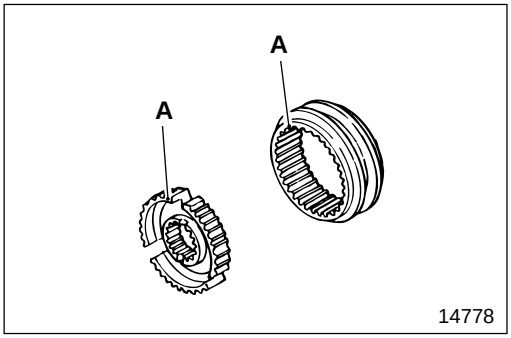
Play of gears in diameter direction

If the measured value is higher than the limit, replace the faulty parts. Also inspect this item after assembly and make sure that the measured value is within the limit.

CAUTION ⚠

Be sure when you replace two needle bearings of a gear, that both needle bearings are from the same color package.

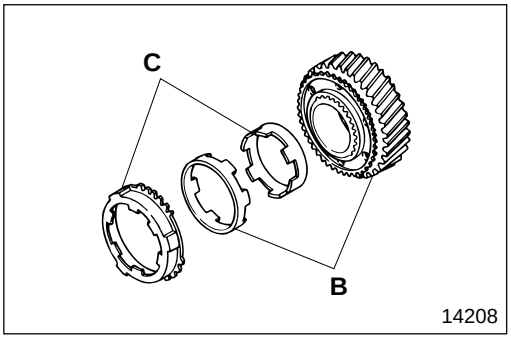
MAINSHAFT ASSEMBLY



[Alignment marks]

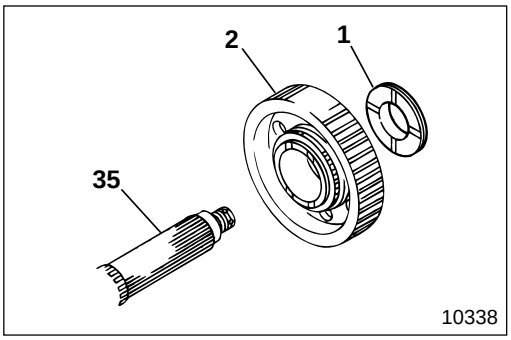
(1) Synchronizer sleeve and synchronizer hub

Before disassembling the synchronizer sleeve and the synchronizer hub, put alignment marks **A** on the places where the shifting keys are installed. When reusing parts, align the alignment marks to assemble.



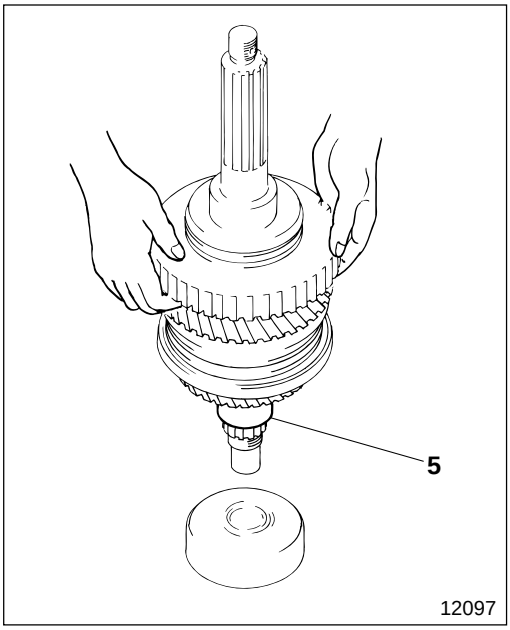
(2) Ring, cone and gear assembly of double cone synchronizer

Before disassembling synchronizer center cone and gear assembly (**B**), and synchronizer center ring and synchronizer outer ring (**C**), put alignment marks on them. When reusing parts, align the alignment marks to assemble.



1 Installation of 1st gear thrust washer

Install 1st gear thrust washer **1** onto mainshaft **35** in the direction as illustrated.



5 21 25 1st, 4th and 3rd gear bearing

[Removal]

Drop mainshaft **35** on a lead block to remove bearing sleeves **5, 21, 25,** making use of the weight of the gears.

CAUTION

Make sure you use a lead block and be careful you do not damage the end of mainshaft 35.

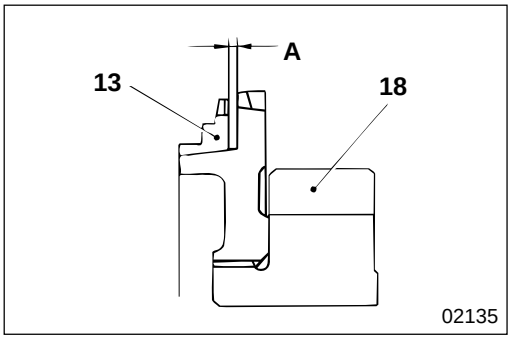
[Inspection]

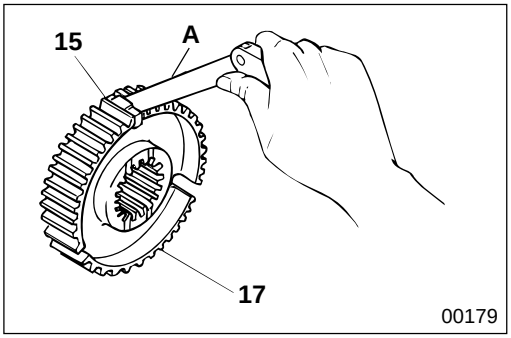
(1) Clearance between the protrusion of synchronizer ring 13 and the groove of synchronizer hub 17

If the measured value is higher than the limit, replace the faulty parts.



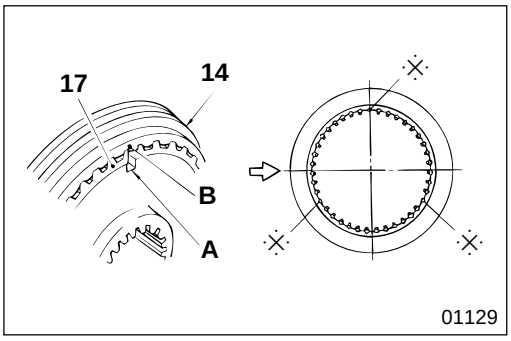
(2) Clearance between synchronizer ring 13 and 4th gear assembly 18 or drive pinion

- Measure clearance **A** between synchronizer ring **13** and the gear cone of 4th gear assembly **18** or drive pinion.
- When measuring this value, press synchronizer ring **13** evenly **1** and measure all around the circumference.
- If the measured value is lower than the limit, replace the faulty parts.



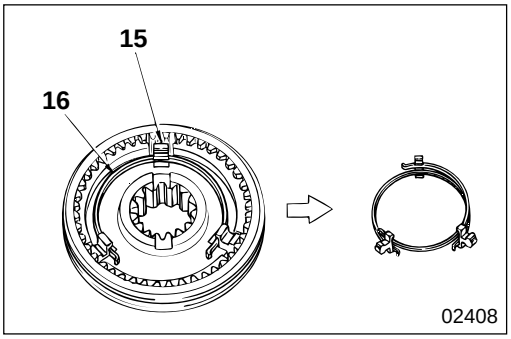
(3) Clearance between shifting key 15 and synchronizer hub 17

If the measured value is higher than the limit, replace the faulty parts.
A : Feeler gauge

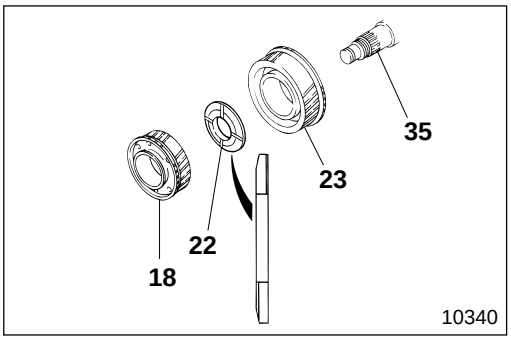


[Installation]

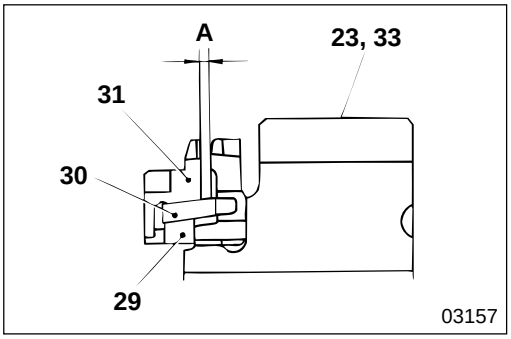
- Align the three keyways **A** of synchronizer hub **17** with the three stub teeth **B** (illustrated by ·⁜· mark) of synchronizer sleeve **14** to install the synchronizer hub.
- To reassemble synchronizer hub **17** and synchronizer sleeve **14**, align the alignment marks made during disassembly.



- Insert shifting key **15** into the keyway.
- Install shifting key spring **16** so that its opening is offset from the one on the shifting key.
- Make sure that the openings of shifting key springs **16** do not align with each other.



22 Installation of thrust washer



23 31 33 Clearance between synchronizer outer ring and 3rd gear assembly or 2nd gear assembly

- Measure clearance **A** between synchronizer outer ring **31** and 3rd gear assembly **23** or 2nd gear assembly cone **33**.
- When measuring this value, press synchronizer inner ring **29**, synchronizer center cone **30** and synchronizer outer ring **31** evenly and measure all around the circumference.
- If the measured value is lower than the limit, replace the faulty parts.

◆ Service procedure

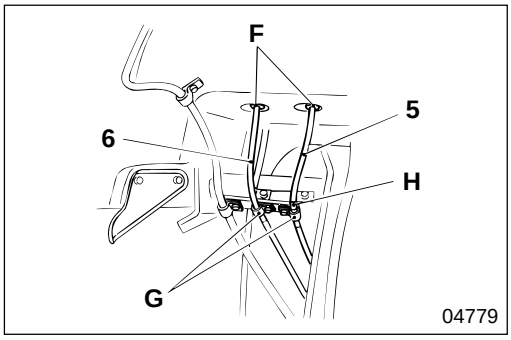
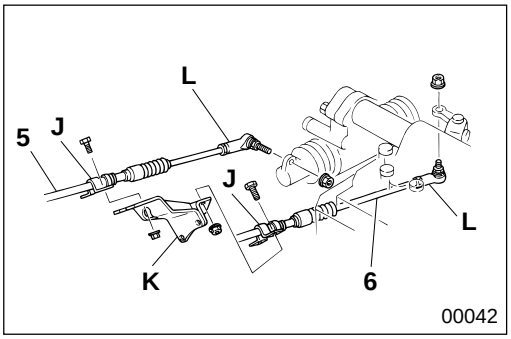
5 **6** **Installation of shift cable and selector cable**

CAUTION⚠

- **Install casing cap A lengthwise.**
- **Make sure the radius of the bend is 200 mm {7.87 in.} or more.**
- **Make sure the cable operates smoothly.**
- **Install the clamp vertically against the cable. (Figure B)**
- **Do not twist clamps C at both ends of the boot. Make sure that white line D on the boot is straight. (Figure E)**



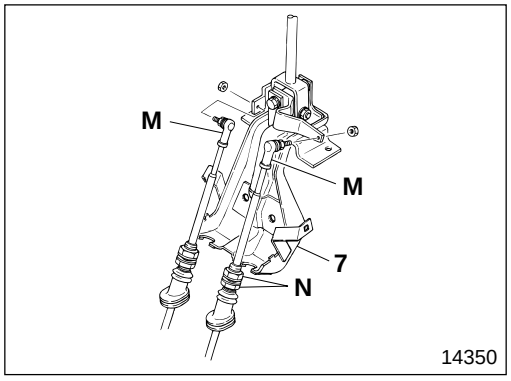
- Insert shift cable **5** and selector cable **6** under the cab floor and clamp them in the correct place by identifying identification mark **H** on the shift cable. (The selector cable has no identification mark.)
  F : Grommet
  G : Clip



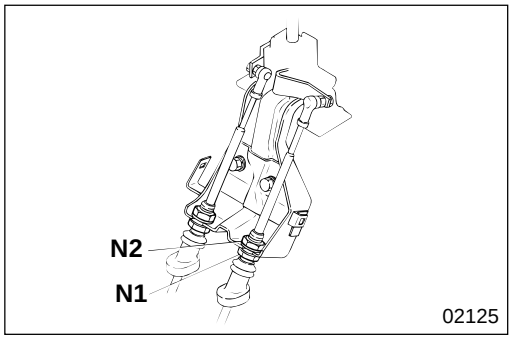
- Install cable clip **J** to bracket **K** temporarily and connect ball joint **L** to the shift lever or selector lever.
- Arrange the cable so that it not twisted, then tighten clip **J** permanently.

CAUTION⚠

Make sure the identification marks on the cable, ball joint L point in the right direction when you install the cables. Installing the cables with the identification marks in the wrong direction can remarkably reduce the durability of the cables.



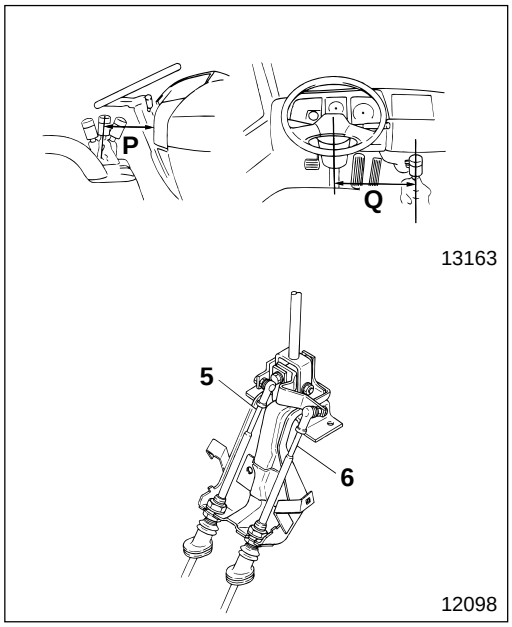
- Tilt the cab down.
- Install the cable on transmission control lever assembly **7** temporarily and connect ball joint **M** to shift lever and selector lever.
- Arrange the cable so that it is not twisted, then tighten lock nuts **N** permanently.



CAUTION⚠

- **Make sure that ball joint P faces the correct direction.**
- **When installing the lock nut, tighten lower nut N1. Do not move nut N2.**

- Make sure when you operate the gear shift lever that it shifts smoothly and selects each position.



- If the gear shift lever leans to the front or rear, or to the left or right, excessively, adjust the length of the cable.
- When positioning the gear shift lever, use the distance from the center of the steering wheel or from the instrument panel as the reference distance.

The automatic transmission consists of a torque converter and a fully automatic 4-speed gear system.

● **Torque converter**

The torque converter is driven by the engine crankshaft, and functions as the input device for the transmission. The torque converter also acts as the fluid coupling, absorbing shock during engine start up and gear shifting.

● **Transmission (4 forward speeds, 1 reverse speed)**

The transmission is accomplished by three sets of planetary gears **18**, **19**, **20** and five sets of oil pressure-operated, wet-type multiple disc clutches **7**, **8**, **9**, **11**, **13**. These oil-cooled clutch discs are self-adjusting to compensate for wear.

● **Oil pressure control area**

This oil pressure control area consists of oil pump **4**, control valve assembly **21** that controls the changeover between clutches **7**, **8**, **9**, **11**, and **13**, the modulator that monitors the amount the accelerator pedal is depressed, and the governor that monitors the vehicle speed. Gear shift is made automatically and depends on how much the accelerator pedal is depressed and how fast the vehicle is travelling.

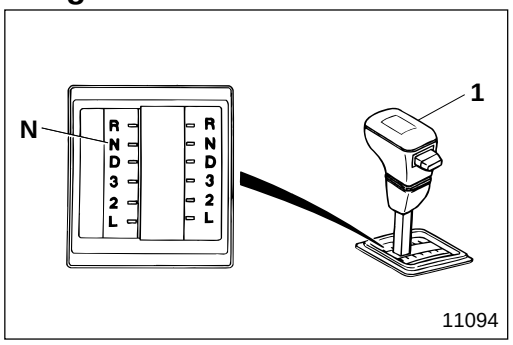
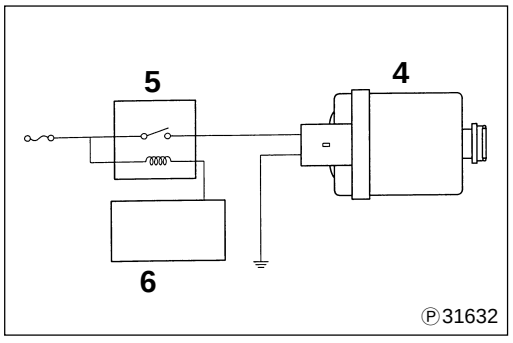
Range Selector Lever



Range selector lever **1** selects the most suitable range for the operating conditions, ensuring optimum service from the automatic transmission. Safety features are incorporated that make sure that the engine cannot be started when the range selector lever is in any position other than neutral (N).

N : Neutral

Modulator



Modulator **4** converts the amount the accelerator pedal is depressed into hydraulic pressure.

- **Outline of operating system**

  Engine electronic control unit **6** sends a signal via relay **5** to activate modulator 4 for switching between closed-throttle shift and full-throttle shift.

- **Operating conditions**

  Throttle opening of 85% or more: ON (Full-throttle shift)
  Throttle opening of 65% or less after ON: OFF (Closed-throttle shift)

- **Automatic transmission fluid temperature sensor**

  Automatic transmission fluid temperature sensor **3** is added due to the use of engine output control mechanism which activates in high automatic transmission fluid temperature conditions.

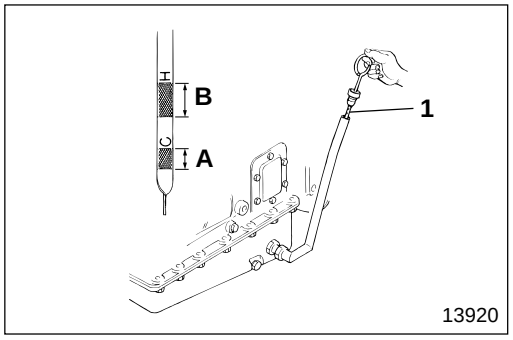
ON-VEHICLE INSPECTION AND ADJUSTMENT

Inspection of Automatic Transmission Fluid

(1) Inspection of characteristics

If the automatic transmission fluid smells burnt or if it contains metal particles or sludge as a result of internal friction and wear of metal or other material, the transmission assembly must be completely overhauled. Make sure you carefully examine the automatic transmission fluid on the dipstick. If you find the quality questionable, take a sample and examine it more closely.



(2) Inspection of automatic transmission fluid level

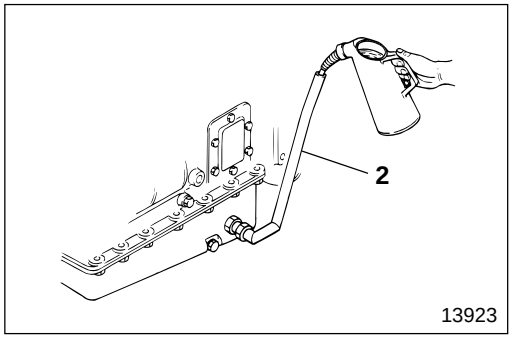
- Park the vehicle on level ground, make sure that the parking brake is fully activated and chock the wheels to keep them from rolling.
- Start the engine and let it idle. To fill the hydraulic circuit with automatic transmission fluid, shift the range selector lever from N → R → N → D → 2 → D → N. Repeat this process five times, finally shifting to N.
- While the engine is still idling, pull out dipstick **1** and wipe off the fluid sticking to it. Reinsert the dipstick, then pull it out again and check the fluid level.
- If the fluid level is inspected right after the engine is started and the fluid temperature is still low (approximately 15 to 49°C {60 to 120°F}), the level should be within area **A** marked COLD on dipstick **1**.
- If the fluid level is inspected after the vehicle has been driven and the fluid temperature is high (approximately 71 to 93°C {160 to 200°F}), the level should be within area **B** marked HOT on dipstick **1**.

WARNING⚠

Take care during the inspection because the engine will be running. Take sufficient care to avoid burns or injuries resulting from contact with moving parts.

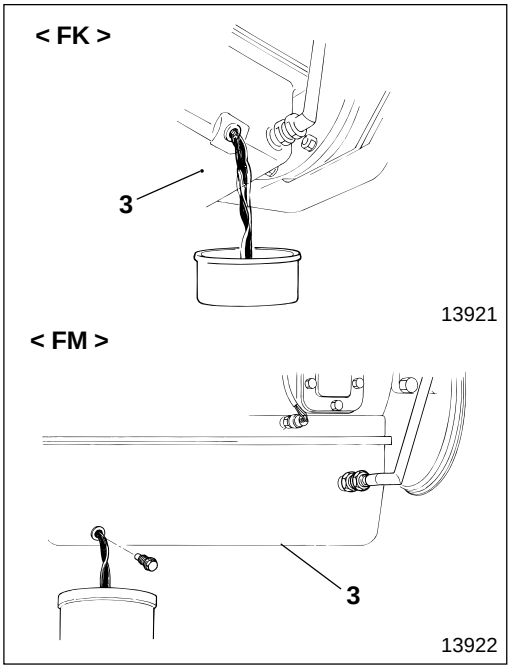
NOTE

- **Make sure the vehicle is parked on level ground when you are checking the fluid level.**
- **Make sure the selector lever is in the N position and the engine is idling when you are checking the fluid level. When the engine is stopped, the fluid level appears higher than it actually is.**
- **Be sure to wipe off the dust from the safety cap and the upper part of dipstick guide 2 before you pull out dipstick 1.**
- **To ensure the fluid is correct, reinspect the fluid level after an actual drive.**



- If the fluid level is low, add automatic transmission fluid (DEXRON or DEXRON II type) through dipstick guide **2** until the correct level on dipstick **1** is reached.

Replacement of Automatic Transmission Fluid



(1) Draining

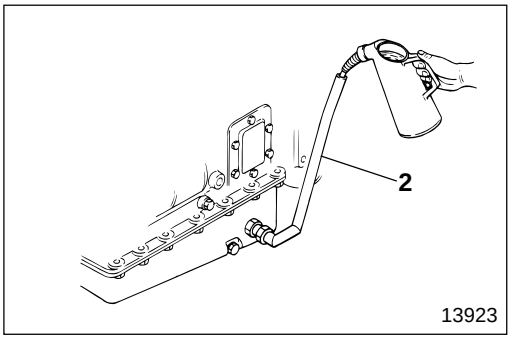
- Park the vehicle on level ground, chock the wheels and shift the selector lever to the **N** position.
- Place a container under oil pan **3**, remove the drain plug and drain the fluid.
- Clean oil pan **3** and the drain plug. Replace the oil filter. P23A-19
- Replace the outer oil filter. P23A-28

WARNING

Take care because the fluid temperature immediately after the engine has stopped is very high. To avoid scalds, wait until a safe temperature has been reached before draining the fluid.

NOTE

- **The fluid will drain faster if the engine is first run to raise the fluid temperature.**
- **The fluid cannot be drained from the hydraulic circuit, the torque converter or the oil cooler.**
- **Check the drained fluid for dirt, metal particles and metal fragments.**



(2) Refill

- Install the oil filter, oil pan **3** and the drain plug. P23A–19
- Add automatic transmission fluid (DEXRON or DEXRON II type) through dipstick guide **2**.
  FK : 8.5 L {9.0 qts}
  FM : 15 L {16 qts}

CAUTION

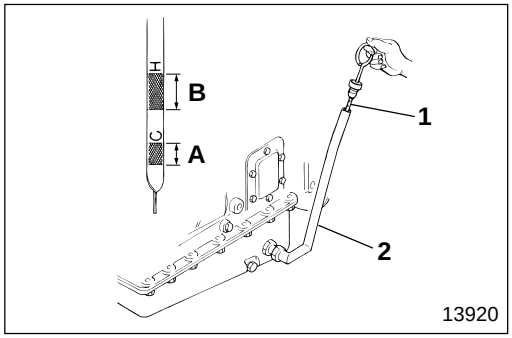
Make sure that dirt and foreign particles do not become mixed in with the fluid when it is added.

- Shift the range selector lever to the **N** position, start the engine and let it idle for about one minute.
- After shifting the lever through all positions once, shift it back to the **N** position.

CAUTION

To prevent burning out the interior of the automatic transmission assembly, make sure that the engine is not allowed to race when you do the above.

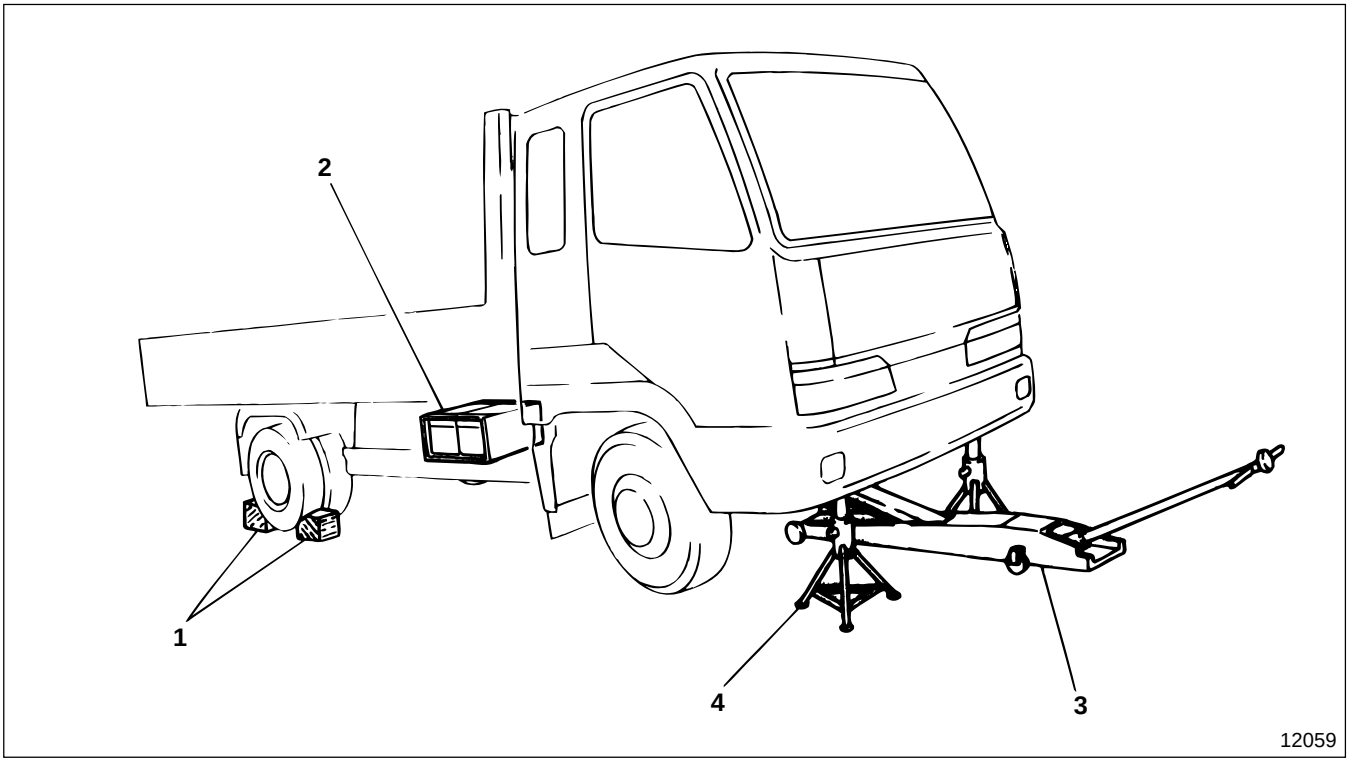
ON-VEHICLE INSPECTION AND ADJUSTMENT



- Check and adjust so that the fluid level is within the specified area on dipstick **1**.

NOTE

- **As the temperature of the fluid rises, so does the fluid level. If you add fluid while the temperature is still low (approximately 15 to 49°C {60 to 120°F}), make sure that the level stays within area A, marked COLD on dipstick 1.**
- **Let the engine idle and, while paying attention to the fluid level, pour in the fluid slowly.**
- **It is sometimes hard to check the fluid level, immediately after supplying fluid, because of the fluid adhering to the interior of dipstick guide 2. If this is the case, check the fluid level several times at intervals.**
- **Be careful not to supply too much fluid because you might mistake the fluid that overflows from the air breather for fluid leakage.**



● **Work sequence before removal**

1 Place wheel chocks.
2 Disconnect the negative battery cable Gr 54
3 Jack up the front axle with a garage jack.
4 Support the front frame on rigid racks.

WARNING⚠

- **The parking brake will be removed so naturally it cannot be used. Chock the wheels securely so the vehicle does not move.**
- **Do not remove the chocks until the entire operation is completed.**
- **Supporting a vehicle on a garage jack only is extremely dangerous, so always support the frame on rigid racks.**
- **Leave the garage jack and rigid racks in place until the entire operation is completed. Never remove them during the operation.**

CAUTION⚠

Be sure to keep the automatic transmission in neutral throughout the operation.

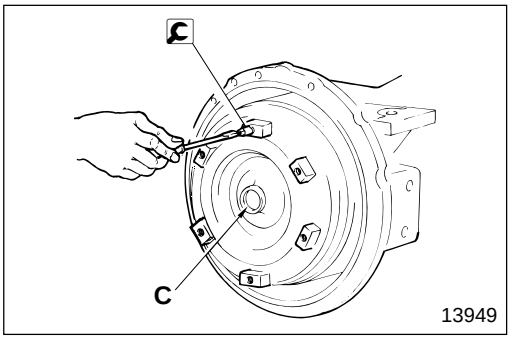
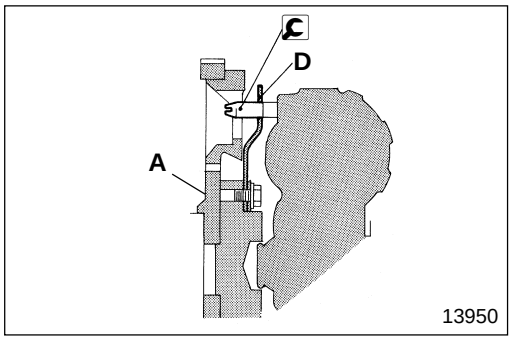
CAUTION

- **Be careful not to apply force unevenly to any of the oil pan parts.**
- **Be careful not to let the torque converter fall from the transmission body because as a single unit the torque converter can come loose easily.**

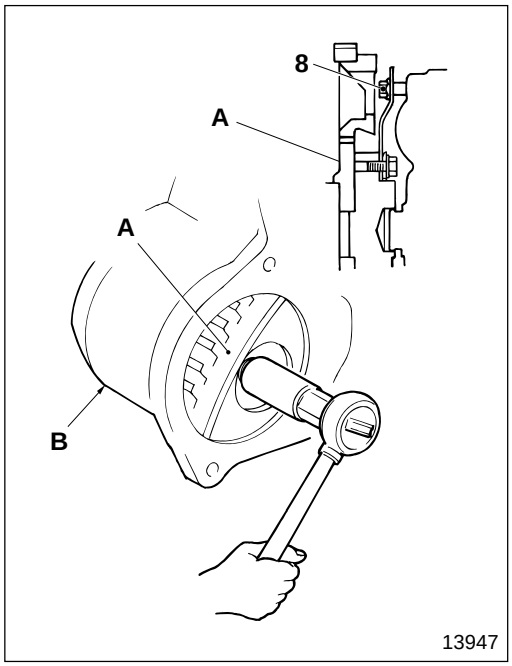


[Installation]

- Apply molybdenum disulfide grease to torque converter pilot area **C**.
- Mount torque converter installer in the tapped hole on the torque converter periphery.



- Install the automatic transmission assembly to the engine flywheel housing, by aligning torque converter installer with the hole in flexplate **D** of flywheel **A**.



- Rotate flywheel **A** and tighten bolts **8**, in sequence, through the working hole of starter housing **B**. (6 points)
- Remove the converter installer and replace it with bolt **8**.
- First tighten all six bolts **8** temporarily, then tighten at specified torque.

NOTE

Be careful not to drop bolts 8 into the gap between flywheel A and the torque converter.

◆ Service procedure

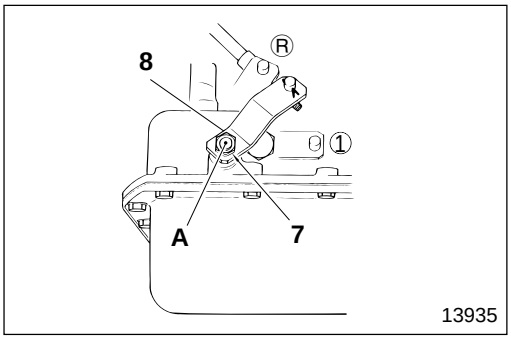
6 **Installation of selector cable**

NOTE

- **Make sure casing cap A is installed in a straight line.**
- **Cable bend radius must be 20 cm {7.87 in.} or more.**
- **Make sure the cable is straight.**
- **Install the clamp at right angles to the cable. (Figure B)**
- **Do not twist clamps D at the ends of boot C. Install so that white line E on the boot is a straight line. (Figure E)**



8 **Installation of selector lever**

If selector lever **8** has been removed, rotate selector shaft **A** and move it to an intermediate position between, but other than, ① and Ⓡ, then tighten nut **7**.

CAUTION⚠

Be careful not to overtighten nut 7, it might cause the internal lever to malfunction.

● **Inspection after installation**

- Make sure that when range selector lever * on the driver's side is operated, the detent positions of selector lever **8** on the automatic transmission side agree with the corresponding positions of the range selector lever on the driver's side. Also make sure that the range selector lever on the driver's side and the selector lever on the automatic transmission side are both operating smoothly.
- Make sure the modulator cable moves smoothly.
- Make sure the starter switch can be operated only in the neutral position, and is disabled for all other positions.
- Make sure the backup lamps light when the selector is in the reverse (R) position.
  (The lamps do not light when the engine is stopped.)

Note: Lock-up point is always set for the gear exceeding the 3rd.

- Revolutions shown in brackets indicates revolutions of transmission.
- The numerical value indicated in Table is calculated for vehicles set with the diff ratio of 6.666 and fitted with 11R22.5 tires. When the diff ratio or the tire size for vehicles is different, the speed of the vehicles varies based on such deviation. So, convert the numerical value in Table based on the applied specifications.

Electronic control (ATEC: Allison Transmission Electronic Control) system is composed of vehicle interface module **2**, automatic transmission electronic control unit **3**, range selector **5**, throttle position sensor, electronic hydraulic valve body, and harnesses connecting these units. The automatic transmission electronic control unit receives electric signals, which are sent by each sensor and shift selector, processes them, transmits the signals to an appropriate solenoid, and thereby controls the transmission.

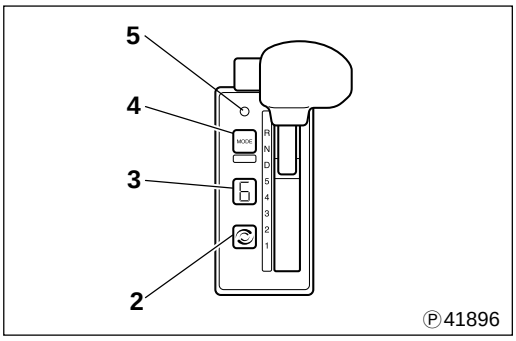
This automatic transmission is equipped with trouble self-diagnosis function. When detecting abnormality, the function displays occurrence of troubles on warning lamp **1**, as well as memorizes the trouble code No. in the memory. A maximum number of five (5) trouble codes are memorized.

Start of trouble mode (reading trouble code No.)

- Push display switch button **2** of range selector twice.
- Trouble code No. is indicated in select position display **3**. If "OL" is indicated, push the display switch button **2** again.
- Record the trouble code No. that is indicated.
  For instance, if indicated in order of "d1", "25", and "11", it shows that main code No. 25 and sub code No. 11 are memorized in the 1st memory. When nothing is recorded, "--" "--" is repeatedly displayed in sequence.
- There are five (5) memories that memorize the code No. When pushing mode button **4**, the 2nd memory code is displayed following "d2".
- Whenever pushing mode button **4**, "d3", "d4", and "d5" are displayed in sequence, and finally "d1" is indicated back.



Clearing of diagnosis trouble code No.

After the repair is completed and mode button **4** is pushed for about 10 seconds, mode lamp **5** will flash for the first 5 seconds and the current malfunction code is cleared. After waiting another 5 seconds, the mode lamp will flash again and the past malfunction codes are cleared.

NOTE

The code No. is cleared only after if the trouble is repaired.

Release of diagnosis mode (returning to normal operation mode)

There are the following three (3) methods to return it to normal operation mode.

- Push the display switch button **2** of range selector.
- Switch it to either range of either range, "Reverse", "Neutral", or "Drive".
- Leave things as they are without doing anything (being automatically released in approximately ten (10) minutes).

ON-VEHICLE INSPECTION AND ADJUSTMENT

1. Stall test

● **Purpose**

"Stall test" checks the friction element in transmission, slide of one-way clutch in torque converter, operation of torque converter, or overall performance of the engine; thereby investigates the cause when the vehicle is malfunctioned due to insufficient power, performance, or others.

● **Measurement procedure**

Before starting the test, check the cooling water and oil of the engine, and automatic transmission fluid level of automatic transmission. Also, conduct sufficient warm-up operation of the engine and transmission.

- Fit the chocks securely at the front (rear) of the front (rear) wheels and engage the parking brake to prevent the vehicle from moving. In addition, when pushing the accelerator pedal down, depress the foot brake strongly.
- Start the engine and engage the range selector lever into D range.
- Push the accelerator pedal down slowly to the full acceleration; when the engine comes into a stable speed at a constant speed, read the revolutions (the stall revolutions) quickly, and then take off the foot from the accelerator pedal.

CAUTION⚠

- **Be sure to set a full stall acceleration time as less than 5 seconds, and complete the measurement during that time.**
- **Be careful for overheating of the engine and transmission.**

- Put the range selector lever in "N" range, and conduct the cooling for two (2) minutes or more per 1000 rpm.
  Stall revolutions
  1750±150 rpm

● **Result of diagnosis**

1. In case the stall revolution is too low; if the result of measurement is lower by 150 rpm or more than the standard value, the engine will be malfunctioned.
2. In case the stall revolution is abnormally low (approximately 1/3 of the specified value) even though the engine has no any trouble like emitting black smoke; there may be some abnormality inside the torque converter (one-way clutch failure).
3. In case the stall revolution is too high; if the result of measurement is higher by 150 rpm or more than the standard value, the cause may be due to the slide inside the transmission, cavitations, the bubbling of automatic transmission fluid, or damage of the torque converter.

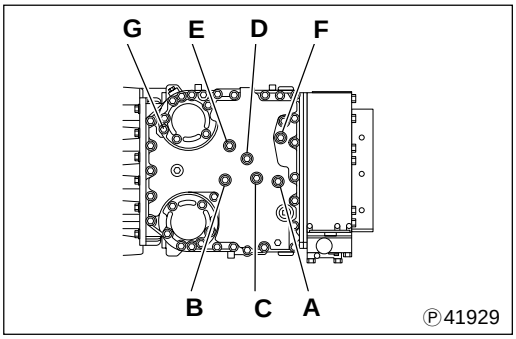
—	Plug	10 to 13 {7.2 to 9.4, 1.0 to 1.3}	—



● Purpose

"Line pressure test" checks the performance of oil pump, function of control valve, and the oil leaking of each component.

● Measurement procedure

Decide the pressure item to check according to the content of troubles, and measure the line pressure based on the following procedure.

- Remove the plug from the pressure detecting port of the gearbox casing, and install the pressure gauge.
  A : Main oil pressure
  B : C1 clutch oil pressure
  C : C2 clutch oil pressure
  D : C3 clutch oil pressure
  E : C4 clutch oil pressure
  F : C5 clutch oil pressure
  G : Lock-up oil pressure
- Conduct a sufficient warm-up operation, and raise oil temperature to 60 to 80°C {140 to176°F}.
- During the idling, measure the oil pressure in each condition when running, and make sure whether the result is within the standard value.
- When making sure the lock-up pressure, remove the propeller shaft, and conduct it in a dummy running condition.
- When having finished the measurement, tighten the plug with the specified torque.

CAUTION⚠

- **Be sure to prevent foreign particles from entering the pressure detecting port.**
- **Remove foreign particles in the pressure detection port before installing the plug.**

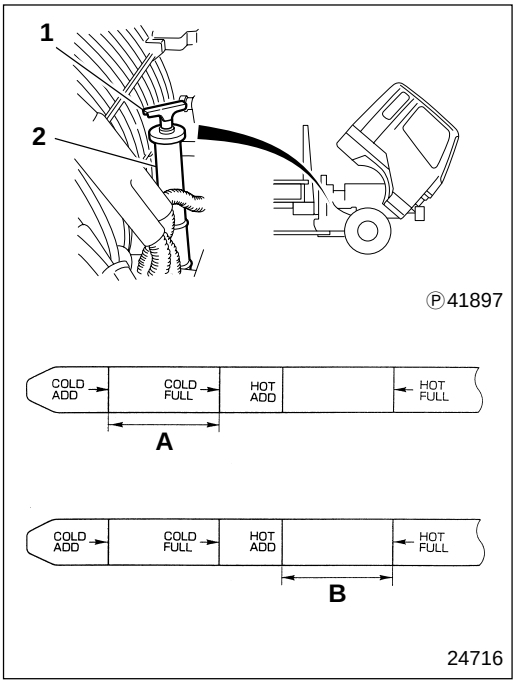
Result of diagnosis

1. In case the main oil pressure is low in all ranges:
   - ATF level; too low
   - Filter Element; clogged
   - Suction filter; clogged
   - Main oil pressure regulator valve; adhered, and the spring; weakening or broken
   - Inside of control module; leaked
   - Oil pump; worn or broken
2. In case the oil pressure is low in the specific ranges (each clutch oil pressure):
   - If C1 clutch pressure is low; may cause slide or judder at 1st, 2nd, 3rd, or 4th gear.
   - If C2 clutch pressure is low; may cause slide or judder at 4th, 5th, or 6th gear.
   - If C3 clutch pressure is low; may cause slide or judder at 3rd, 5th, or Rev. gear.

- If C4 clutch pressure is low; may cause slide or judder at 2nd, or 6th gear.
- If C5 clutch pressure is low; may cause slide or judder at 1st or Rev. gear.
- If the lock-up clutch pressure is low; the speed extension of vehicle at 2nd or more gear (in lock-up) may be decreased. Or, the shift will not be performed as it is a shift map.

3. Inspection of automatic transmission fluid



(1) Inspection of characteristics

If the automatic transmission fluid smells burnt or if it contains metal particles or sludge as a result of internal friction and wear of metal or other material, the transmission assembly must be completely overhauled. Make sure you carefully examine the automatic transmission fluid on the dipstick. If you find the quality questionable, take a sample and examine it more closely.

(2) Inspection of automatic transmission fluid level

- Park the vehicle on level ground, make sure that the parking brake is fully activated and chock the wheels to keep them from rolling.
- Start the engine and let it idle. To fill the hydraulic circuit with automatic transmission fluid, shift the range selector lever from N → R → N → D → 2 → D → N. Repeat this process five times, finally shifting to N.
- While the engine is still idling, pull out dipstick **1** and wipe off the fluid sticking to it. Reinsert the dipstick, then pull it out again and check the fluid level.
- If the fluid level is inspected right after the engine is started and the fluid temperature is still low (approximately 15 to 49°C {60 to 120°F}), the level should be within area **A** marked COLD on dipstick **1**.
- If the fluid level is inspected after the vehicle has been driven and the fluid temperature is high (approximately 71 to 93°C {160 to 200°F}), the level should be within area **B** marked HOT on dipstick **1**.

WARNING

Since the inspection is conducted with running the engine, be careful of being caught in components, burn hazard, or the safety.

NOTE

- **Make sure to inspect the quantity of automatic transmission fluid at the horizontal level.**
- **Make sure to inspect the quantity of automatic transmission fluid with idling the engine at N range since the apparent quantity of automatic transmission fluid increases in a state of the engine stop.**
- **Remove any dirt of the protection cap and the upper part of filler tube 2 completely before pulling the level gauge 1 out.**
- **Do not raise the engine speed with keeping the engine in a state of idling until the adjustment of quantity of automatic transmission fluid is completed.**

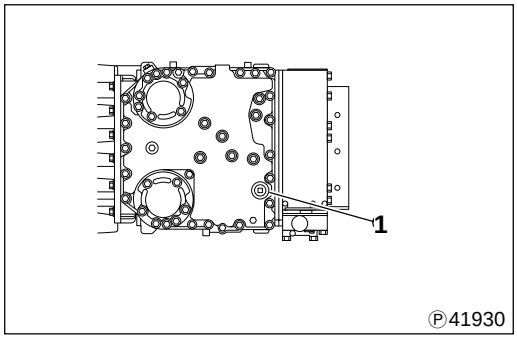
• Reconfirm the automatic transmission fluid level after the vehicle runs actually. In case the quantity of automatic transmission fluid is insufficient, replenish DEXRON III to the specified level of level gauge 1 using filler tube 2.

4. Replacement of automatic transmission fluid

Ⓣ Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
—	Drain plug	25 to 32 {18 to 24, 2.6 to 3.3}	—



(1) Draining

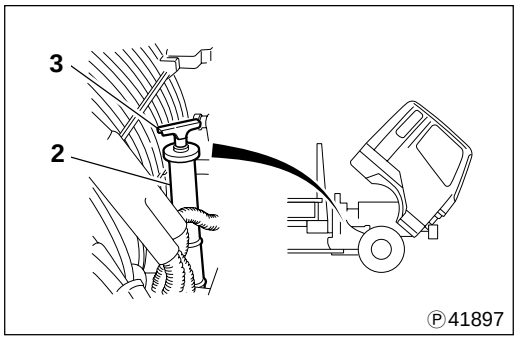
- Park the vehicle on level ground, chock the wheels and shift the selector lever to the **N** position.
- Place a container under oil pan **3**, remove the drain plug and drain the fluid.
- Clean oil pan **3** and the drain plug. Replace the oil filter. 🕮 P23A-19
- Replace the outer oil filter. 🕮 P23A-28

WARNING⚠

Take care because the fluid temperature immediately after the engine has stopped is very high. To avoid scalds, wait until a safe temperature has been reached before draining the fluid.

NOTE

- **The fluid will drain faster if the engine is first run to raise the fluid temperature.**
- **The fluid cannot be drained from the hydraulic circuit, the torque converter or the oil cooler.**
- **Check the drained fluid for dirt, metal particles and metal fragments.**

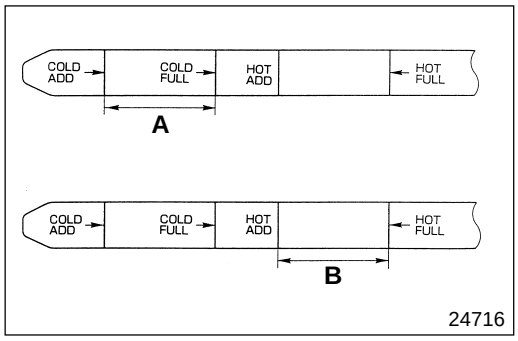


(2) Refill

- Install the oil filter, oil pan **3** and the drain plug. 🕮 P23A–19
- Add automatic transmission fluid (DEXRON or DEXRON II type) through dipstick guide **2**.
  FK : 8.5 L {9.0 qts}
  FM : 15 L {16 qts}

CAUTION⚠

Make sure that dirt and foreign particles do not become mixed in with the fluid when it is added.



- Shift the range selector lever to the **N** position, start the engine and let it idle for about one minute.
- After shifting the lever through all positions once, shift it back to the **N** position.

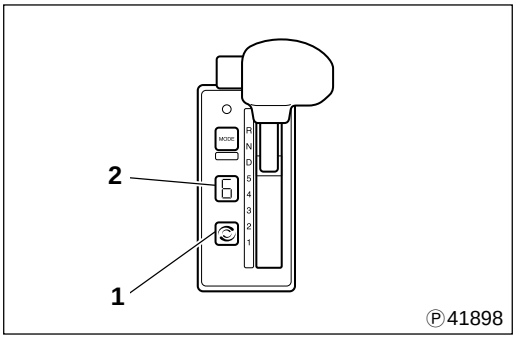
CAUTION⚠

To prevent burning out the interior of the automatic transmission assembly, make sure that the engine is not allowed to race when you do the above.

NOTE

- **After adding automatic transmission fluid, it may be difficult to see the level of automatic transmission fluid easily due to the automatic transmission fluid adhering to the inner wall of filler tube 2; therefore, reconfirm it after a short time.**
- **If overfilling automatic transmission fluid, the automatic transmission fluid begins to overflow from the air breather; as result, it might be misunderstood that the leakage of automatic transmission fluid be caused.**
- **Add automatic transmission fluid gradually, letting the engine idle, while paying careful attention to the level of automatic transmission fluid.**

5. Level check of automatic transmission fluid



This automatic transmission can check automatic transmission fluid level by operating the range selector.

Conditions required on check

- Stop the vehicle at the flat place, and put the range selector in “N” position.
  (Neutral must be selected.)
- Automatic transmission fluid must be warm.
  (oil temperature 60 to 104°C {140 to 219°F})
- Stabilize oil level at intervals of two (2) minutes or more after stopping the vehicle.
- Allow the engine to idle.

Check operation

- Push display switch button 1 of the range selector
- Various code No. are displayed in the position display 2 of the selector following “O” and “L” (indicating check mode of automatic transmission fluid level) after approximately two (2) minutes.

Judgment of check result

The code No. indicated means as follows:

- “OL”, “OK”, and “--” ; automatic transmission fluid level is appropriate.
- “OL”, “LO”, and “XX”; automatic transmission fluid must be added by approximately XX liter.
- “OL”, “HI”, and “XX”; automatic transmission fluid must be extracted by approximately XX liter.
- “OL”, “--”, and “XX” ; check the level again based on the following table since the level could not be checked.

Display code No. XX	Contents
“50”	The engine speed is too low.
“59”	The engine speed is too high.
“65”	Range selection hot in neutral.
“70”	Oil temperature is too low.
“79”	Oil temperature is too high.
“89”	The output shaft rotates.
“95”	Trouble of oil temperature sensor

Operation after the check has ended.

After the check has ended, put the range selector in either of position, “Reverse”, “Neutral”, or “Drive”.

● **Work before removal**

WARNING⚠

- **Since the propeller shaft will be removed, the parking brake (center parking brake) cannot be used. Therefore, you must chock the wheels securely so the vehicle does not move.**
- **Do not remove the chocks until the entire operation is completed.**

Remember to make alignment marks **A** before removal.

◆ Service procedure

● **Inspection before disassembly**

Clearance in axial direction for spider

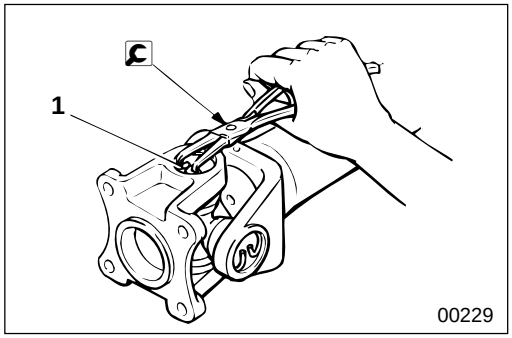
Press needle bearing **2** downward firmly, and measure the clearance between snap ring **1** and the needle bearing. If the measured value is higher than the standard value, adjust it by changing the thickness of the snap ring.

- Available snap ring thicknesses

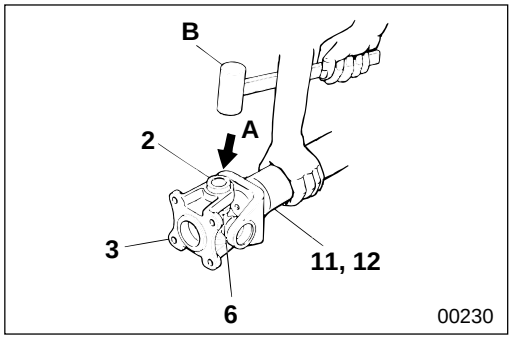
Part name	Thickness	Identification color
Snap ring A	2.5 mm {0.098 in.}	Green
Snap ring B	2.6 mm {0.10 in.}	Red

NOTE

For snap ring 1, it is recommended that you use rings with the same thickness on both ends to ensure balanced revolution.

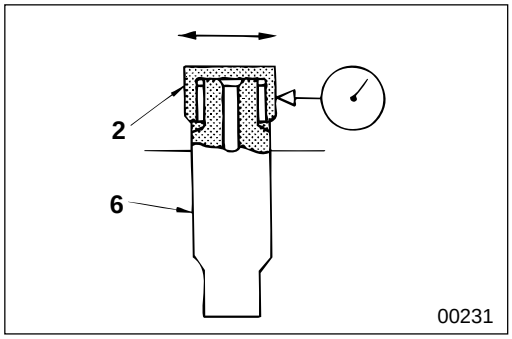


1 **Removal and installation of snap ring**



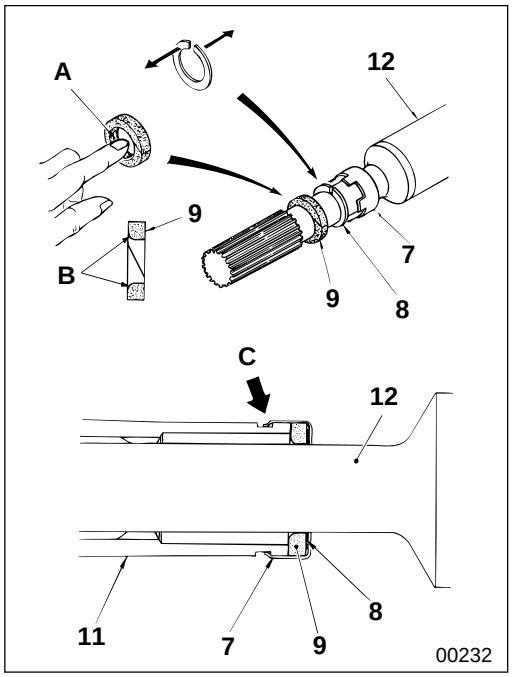
2 **Removal of needle bearing**

- Put alignment marks on needle bearing **2** and spider **6**.
- Put alignment marks across flange yoke **3**, slip yoke joint **11** and rear propeller shaft **12**.
- Hit the yoke lightly at shoulder area **A** so that needle bearing **2** bounces out due to reaction.
  B : Mallet



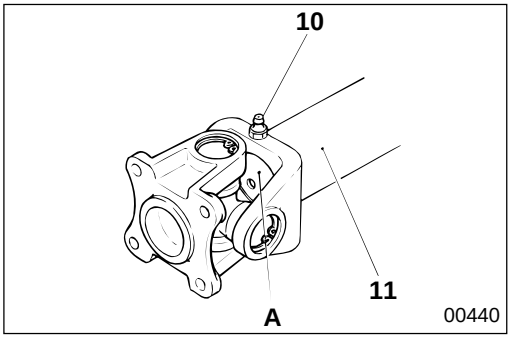
2 **6** **Clearance between needle bearing and spider**

Measure the play towards the diameter direction between needle bearing **2** and spider **6**. If the measured value is higher than the limit, replace with universal joint spider kit.



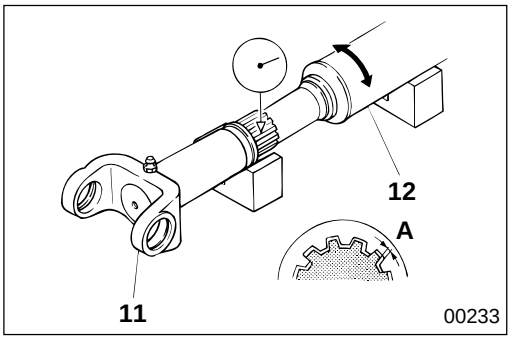
7 **to** **9** **Assembly of dust cap, retainer and cork seal**

- Insert dust cap **7** into rear propeller shaft **12** and expand retainer **8** carefully to mount it on the propeller shaft. Then, release the retainer and allow it to return to its original shape.
- Apply grease to inner surface **A** of cork seal **9**, face its chamfered side **B** towards the spline and mount in the same way as retainer **8**.
- Press cork seal **9**, compressing it by 1 to 2 mm {0.039 to 0.079 in.}, against slip yoke joint **11**, then caulk pawl area **C**.



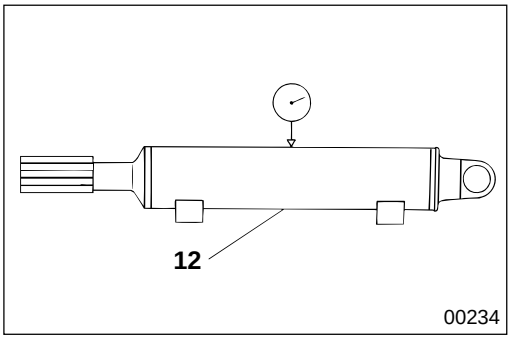
10 **Supply of grease via grease nipple**

Pack grease via grease nipple **10** until grease starts overflowing from the hole in dust plug **A** of slip yoke joint **11**.



11 **12** **Play between slip yoke joint and rear propeller shaft spline in rotating direction**

Measure play **A** in the rotation direction between slip yoke joint **11** and rear propeller shaft **12** at the spline area. If the measured value is higher than the limit, replace the faulty parts.



12 **Bend of rear propeller shaft**

Measure bend of rear propeller shaft **12** at its center. If the measured value is higher than the limit, correct or replace it.

CAUTION

Be sure to check for cracks at the welded area after straightening has been done by means of a press.

NOTE

To measure the bend of rear propeller shaft 12, turn it one full revolution and read the dial gauge indicator. The bend is one half of the indicated value.

Clearance in axial direction for spider

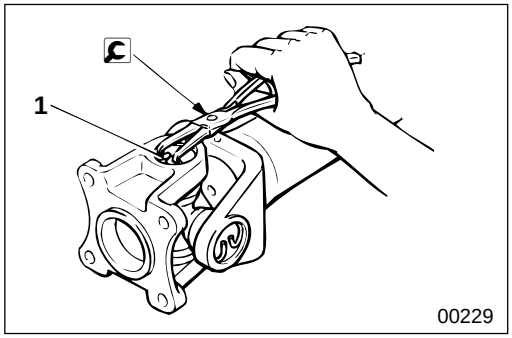
Press needle bearing **2** downward firmly, and measure the clearance between snap ring **1** and the needle bearing. If the measured value is higher than the standard value, adjust it by changing the thickness of the snap ring.

- Available snap ring thicknesses

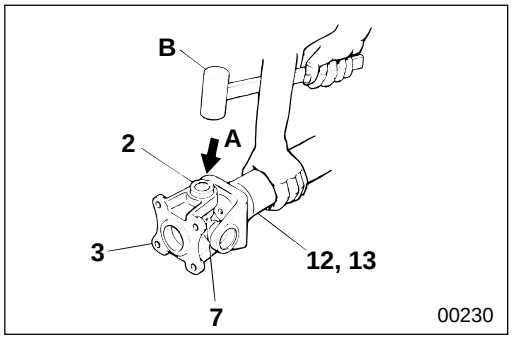
Part name	Thickness	Identification color
Snap ring A	3mm {0.118 in.}	Green
Snap ring B	3.05mm {0.120 in.}	White
Snap ring C	3.1mm {0.122 in.}	Red
Snap ring D	3.15mm {0.124 in.}	Blue
Snap ring E	3.2mm {0.126 in.}	Yellow

NOTE

For snap ring 1, it is recommended that you use rings with the same thickness on both ends to ensure balanced revolution.

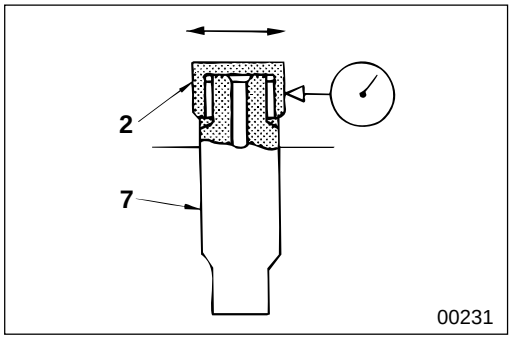


1 **Removal and installation of snap ring**



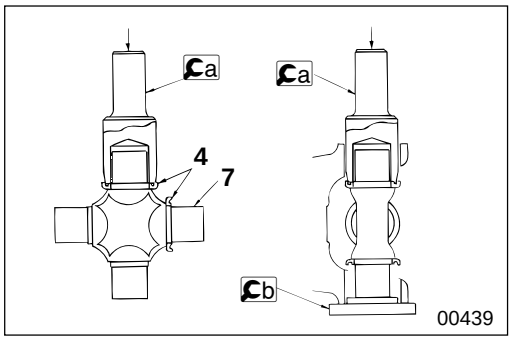
2 **Removal of needle bearing**

- Put alignment marks on needle bearing **2** and spider **7**.
- Put alignment marks across flange yoke **3**, slip yoke joint **12** and rear propeller shaft **13**.
- Hit the yoke lightly at shoulder area **A** so that needle bearing **2** bounces out due to reaction.
  B : Mallet

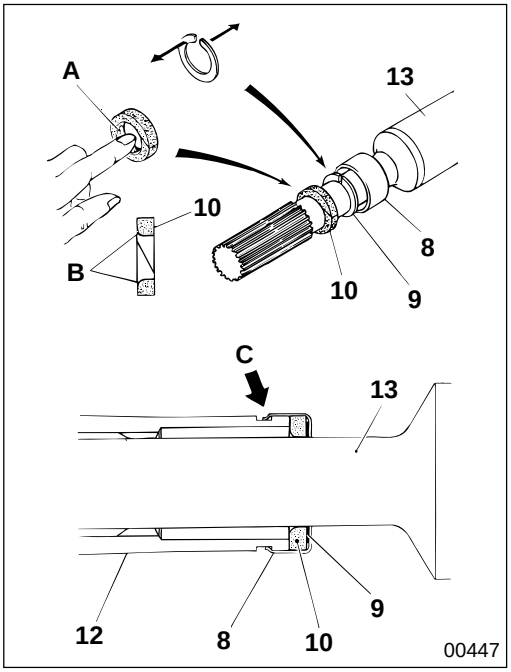


2 **7** **Clearance between needle bearing and spider**

Measure the play towards the diameter direction between needle bearing **2** and spider **7**. If the measured value is higher than the limit, replace with universal joint spider kit.

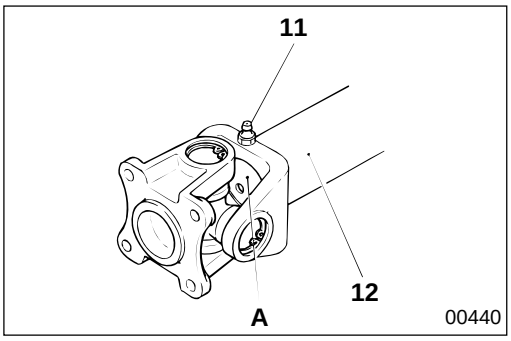


4 **Mounting of dust seal**



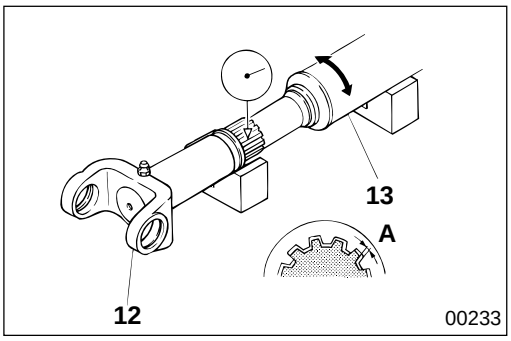
8 **to** **10** **Assembly of dust cap, retainer and cork seal**

- Insert dust cap **8** into rear propeller shaft **13** and expand retainer **9** carefully to mount it on the propeller shaft. Then, release the retainer and allow it to return to its original shape.
- Apply grease to inner surface **A** of cork seal **10**, face its chamfered side **B** towards the spline and mount in the same way as the retainer.
- Press cork seal **10**, compressing it by 1 to 2 mm {0.039 to 0.079 in.}, against slip yoke joint **12**, then caulk area **C**.



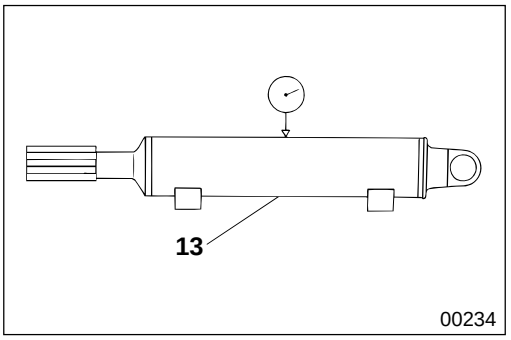
11 **Supply of grease via grease nipple**

Pack grease via grease nipple **11** until grease starts overflowing from the hole in dust plug **A** of slip yoke joint **12**.



12 **13** **Play between slip yoke joint and rear propeller shaft spline in rotating direction**

Measure play **A** in the rotation direction between slip yoke joint **12** and rear propeller shaft **13** at the spline area. If the measured value is higher than the limit, replace the faulty parts.



13 **Bend of rear propeller shaft**

Measure bend of rear propeller shaft **13** at its center. If the measured value is higher than the limit, correct or replace it.

CAUTION

Be sure to check for cracks at the welded area after straightening has been done by means of a press.

NOTE

To measure the bend of rear propeller shaft 13, turn it one full revolution and read the dial gauge indicator. The bend is one half of the indicated value.

Adjustment after Assembly

(1) After any correction has been made of propeller shaft deflection, or replacement of flange yoke and universal joint, adjust the amount of balance of completed propeller shaft assembly on a balancing machine, and make adjustment by installing a balance piece(s) so that the amount comes within the permissible limit.

(2) There are two methods of correcting dynamic balance: the polar coordinate system method, and the 90-degree component force method.
Polar coordinate system method: P4, P8, P10
90-degree component force method: P10

(3) Permissible amount of unbalance
0.49 N·cm {0.0036 lbf.ft, 50 gf·cm}/1600 rpm (Pipe outer periphery)

NOTE
When adjusting a propeller shaft with a large amount of deflection, the 90-degree component force < P10 > method is preferred since this method requires a smaller number of balance pieces.

(4) Method of correction by way of polar coordination method

A : Rear propeller shaft
B : Front propeller shaft
C : Balance piece attachment point
D : Aligning mark

ON-VEHICLE INSPECTION AND ADJUSTMENT

Adjustment of Wheel Alignment

Service standards

Unit : mm {in.}

Location	Maintenance item		Standard value	Limit	Remedy
—	Wheel alignment	Toe-in (with tires on the ground)	0±1 {0±0.039}	—	Adjust
		Camber FK	1°30'±1°00'	—	Adjust
		Camber FM	1°00'±1°00'	—	Adjust
		Caster	2°30' $^{+1°30'}_{-1°00'}$	—	Adjust
		Kingpin inclination angle	7°00'	7°00'±30'	Replace

Tightening torque

Unit : N·m {ft.lbs, kgf·m}

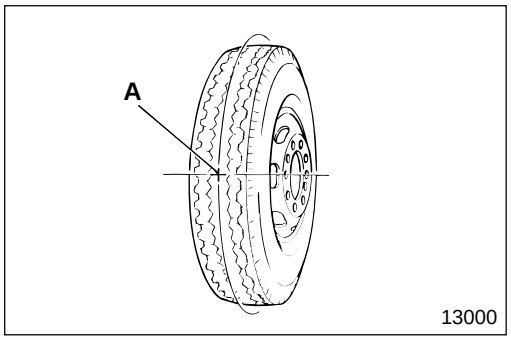
Location	Parts to be tightened		Tightening torque	Remarks
1	Nut (Tie rod end clamp fastening)	FK	78 {58, 8}	Wet
		FM	78 {58, 8}	—

NOTE

- **Measure the wheel alignment when the vehicle is empty and level.**
- **Be sure that each part of the front axle has been serviced perfectly before adjusting the wheel alignment.**

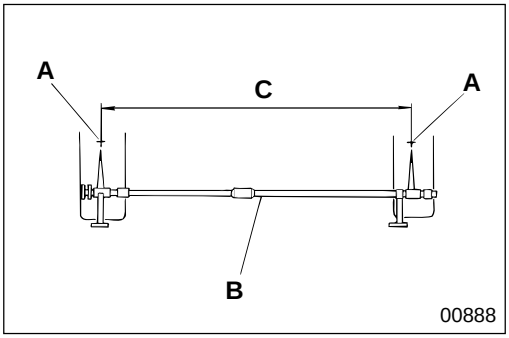
Before adjusting the wheel alignment, check for the following faults:

- Play in front wheel hub
- Play or looseness in kingpin
- Play or looseness in the joint between the tie rod and the knuckle arm
- Looseness of any fasteners
- Fatigued or damaged leaf springs
- Incorrect tire pressure
- Incorrect power steering booster backlash

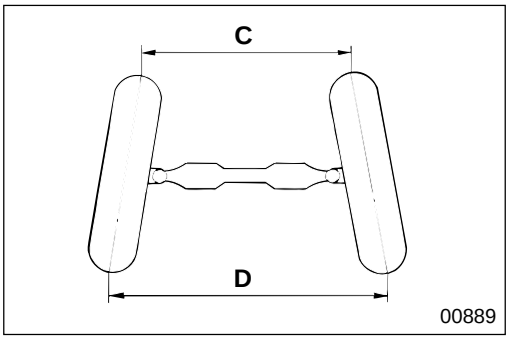


(1) Measurement and adjustment of toe-in

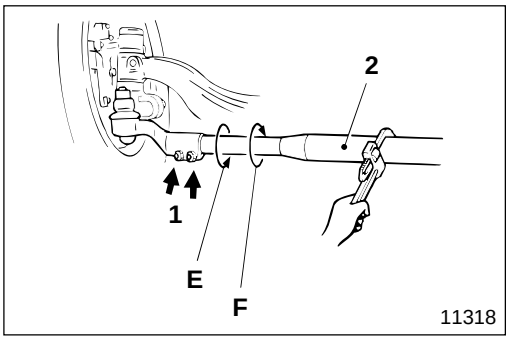
- Point the front wheels exactly forward.
- Put mark **A** on the left and right front tires at the height of front wheel axis and in the middle of the tire width.



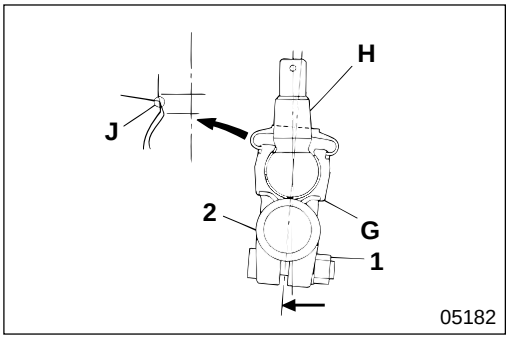
- Align the two points of toe-in gauge **B** to the respective marks **A** on the front tires. Measure the distance **C** between the marks at the front of the vehicle.



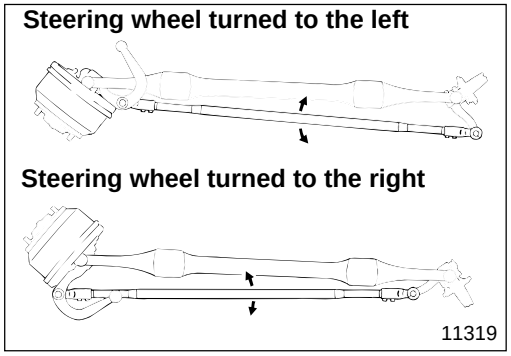
- Rotate the tires 180° and measure distance **D** between the marks at the rear of the vehicle with the tires on the ground.
- Check if the difference between distances **C** and **D** is within the standard value.



- If the measured value deviates from the standard value, with the tires pointed forward, loosen all four left and right tie rod nuts **1**.
- Adjust the toe-in to the standard value by turning tie rod **2** with a pipe wrench.
  E : Adjusting to the toe-out direction
  F : Adjusting to the toe-in direction
  (★ : If tie rod **2** does not swing after the adjustment on 📖 P26-10, redo from this item.)



- Hold down tie rod **2** toward the front or rear of the vehicle so that left and right tie rod ends **G** are in contact **J** with ball studs **H** at the same time. In this state tighten four nuts **1**.
- When tightening nuts **1**, do not let tie rod ends **G** move toward the front or rear of the vehicle.
- When you are working on your own: first tighten nut **1** on one tie rod end **G**, then tighten the nut on the other tie rod end. When you tighten the nuts, make sure you hold down tie rod **2** towards the same direction each time.

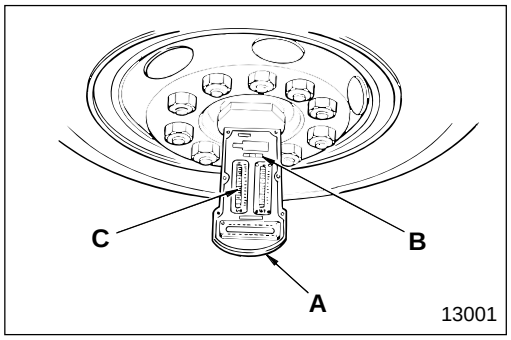


- After adjustment, turn the steering wheel fully to the left until the knuckle stopper bolt is hit. In this state, shake tie rod **2** to check that you can move it toward the front or rear of the vehicle.
  Carry out the same inspection on the right side.
  (Movability of the tie rod indicates that tie rod ends **G** are in contact with ball studs **H** at the same time.)

WARNING⚠

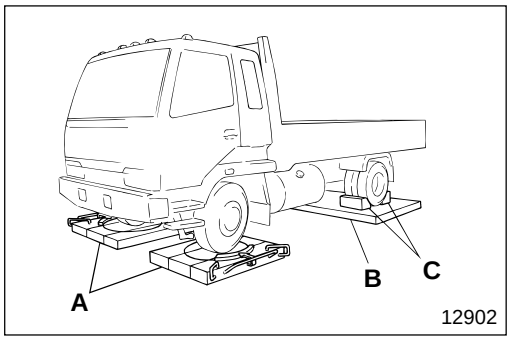
Be very careful that your hand, or anything else, is not caught due to the movement of the tie rod when the steering wheel is turned left and right.

- If tie rod **2** does not swing, redo the procedure from the item marked ★. 📖 P26-9



(2) Measurement of camber

- Point the front wheels exactly forward.
- Remove the wheel hub caps < FK > or the wheel hub covers < FM >.
- Wipe off grease from the knuckle end, and attach camber/caster /kingpin gauge **A** to the front wheel hub.
- While keeping the bubble in level **B** centered, measure the camber angle by reading the scale mark at the center of the bubble on camber scale **C**. Follow this procedure to measure the camber angles on the left and right sides.

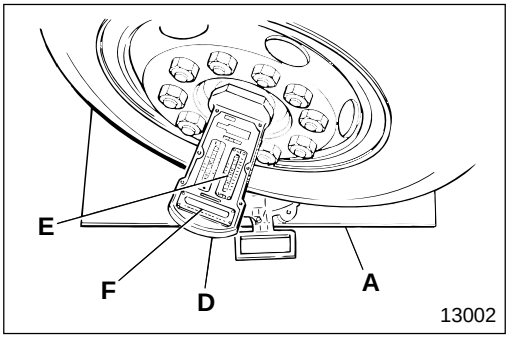


(3) Measurement of caster and kingpin inclination angle

- Align turning radius gauges **A**. Prepare a platform **B** having the same height as the turning radius gauges and place the platform under the rear wheels so that the vehicle is kept level.
- Keep turning radius gauges **A** locked.
- Jack up the vehicle and set the left and right front wheels so that the ground contact area of both front tires and the turntables of turning radius gauge **A** meet at their respective centers.

WARNING⚠

- **After jacking up the vehicle, chock the rear wheels securely with chocks C.**
- **Do not remove chocks C until the entire operation is completed.**



- Unlock turning radius gauge **A**, and set the scale to 0°.
- As in measuring camber explained previously, attach camber/caster kingpin gauge **D** tightly to the front wheel hub and keep the bubble centered.
- Apply the brake to the front wheels and turn the steering wheel slowly from the 0° point on the scale of turning radius gauge **A**, until direction changes 20° to the left for the left front wheel and 20° to the right for the right front wheel.

NOTE

It is not possible to obtain an exact reading of camber unless the brake is applied to the front wheels because the tires might rotate slightly.

- At the 20° point, align the bubbles in caster scale **E** and kingpin scale **F** to 0° by turning the adjuster.

NOTE

Kingpin scale F has scales for left and right; use the left scale when adjusting the left wheel, and the right scale when adjusting the right wheel.

- Turn the steering wheel slowly until the left front wheel changes its direction 20° to the right, or until the right front wheel changes its direction 20° to the left, past the 0° point of turning radius gauge **A** scale. At this point read the scale marks at the center of the bubbles on caster scale **E** and kingpin scale **F**. The scale marks indicate the caster and kingpin inclination angles.

ON-VEHICLE INSPECTION AND ADJUSTMENT

Adjustment of Steering Angle

Service standards

Location	Maintenance item			Standard value	Limit	Remedy
—	Steering angle	Inside (Outside : reference)	FK617	43° (33°57')	—	Adjust
			FM617	40° (34°38')	—	Adjust
			FM657	44° (35°44')	—	Adjust

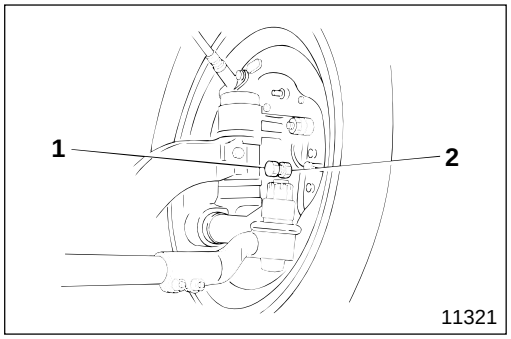
Ⓣ Tightening torque

Unit : N·m {ft.lbs, kgf·m}

Location	Parts to be tightened	Tightening torque	Remarks
2	Lock nut (Knuckle stopper bolt fastening)	71±12 {52±9, 7.25±1.25}	—

NOTE

Be sure that wheel alignment is adjusted perfectly before adjusting the steering angle.

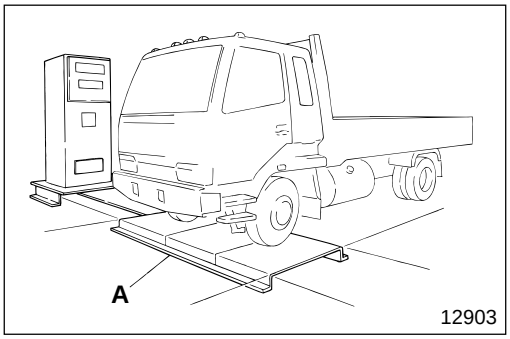


- To adjust the steering angle, set the turning radius gauges and platform in the same way as for caster and kingpin inclination angle measurement.
- Turn the steering wheel to the left or right completely, and from the position where the turning radius gauge is aligned to 0°, adjust knuckle stopper bolt **1**. Adjust so that the steering angle is within the standard inside steering angle value, to the left for the left front wheel, and to the right for the right front wheel. Then, tighten lock nut **2** at specified torque.

Measurement of Side Slip

NOTE

Be sure that wheel alignment is adjusted fully before measuring side slip.

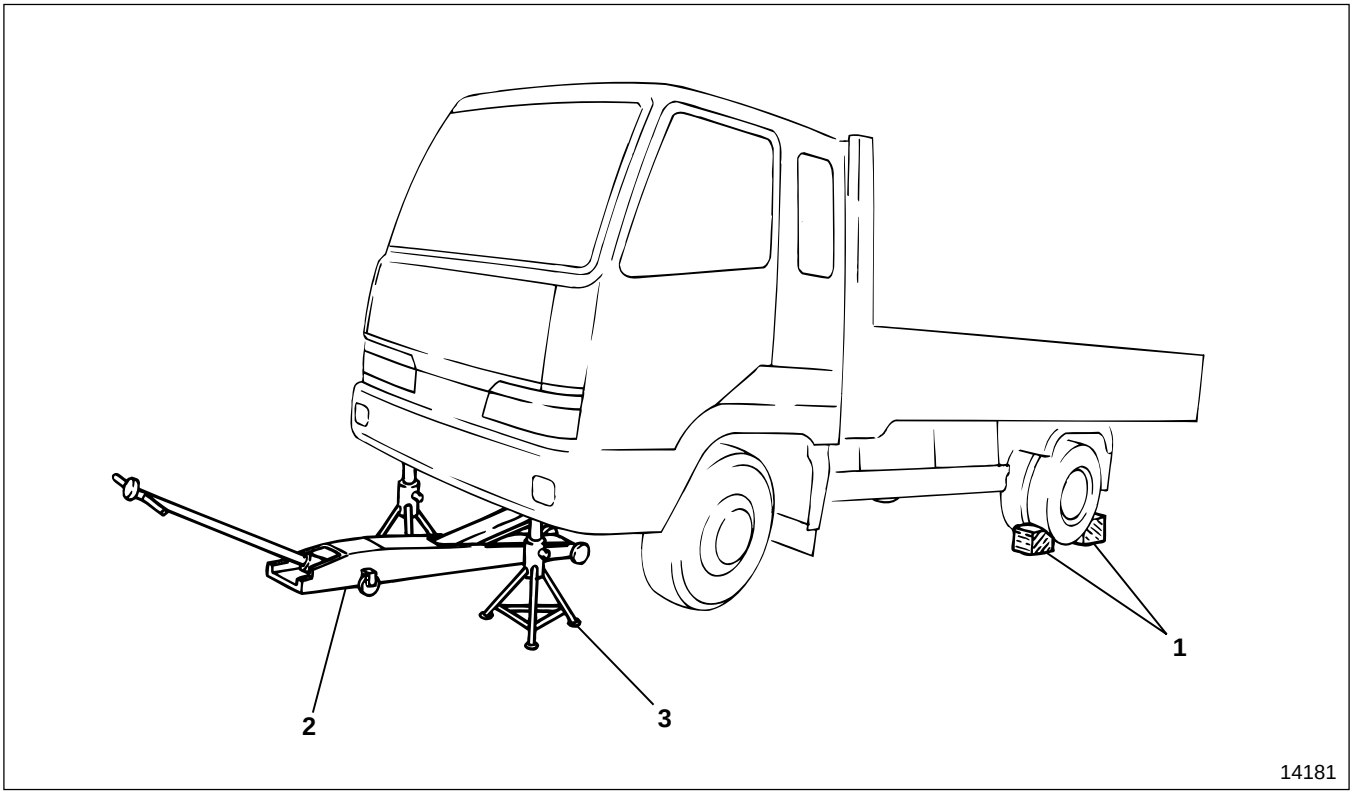


- Point the front wheels exactly forward.
- Maintain this position and slowly move vehicle forward, over side slip tester **A**, as slowly as possible.

NOTE

Make sure, when measuring side slip, that the wheels point exactly forward when the vehicle passes over side slip tester A. Do not allow the wheels to veer from side-to-side.

- The side slip is indicated by side slip tester **A** after the vehicle has passed through the tester. Readjust wheel alignment if slippage is 3 mm {0.12 in.} or more per meter {3.28 ft.}.



● **Work sequence before removal**

1 Place wheel chocks.
2 Jack up the front axle with a garage jack.
3 Support the front frame on rigid racks.

WARNING

- **Chock the wheels securely so the vehicle does not move.**
- **Do not remove the chocks until the entire operation is completed.**
- **Supporting a vehicle on a garage jack only is extremely dangerous, so always support the frame on rigid racks.**
- **Leave the garage jack and rigid racks in place until the entire operation is completed. Never remove them during the operation.**

● **Work sequence after installation**

Follow the work sequence before removal in reverse.

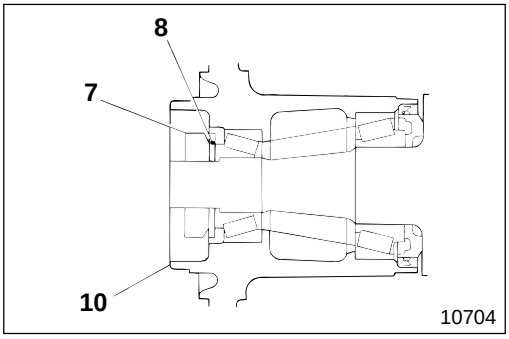
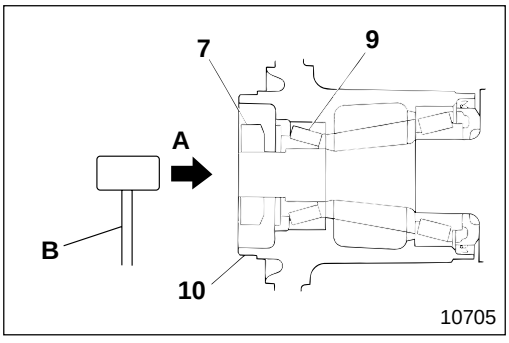
◆ Service procedure



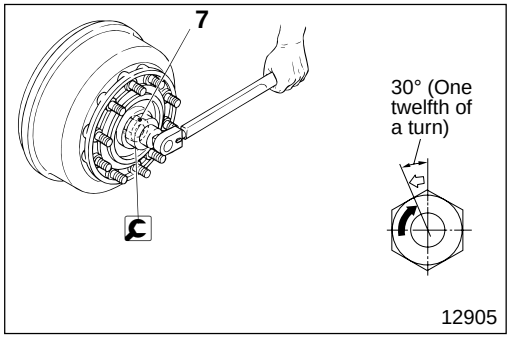
● Starting torque of wheel hub drum

[Adjustment]

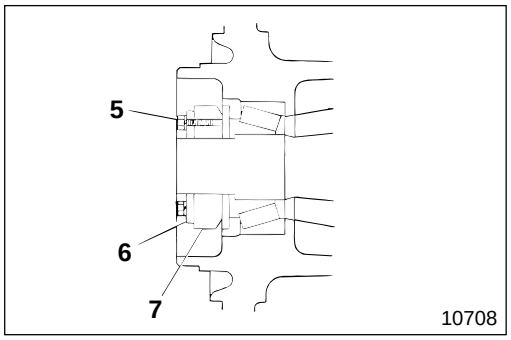
- Install lock washer **8** and lock nut **7**, then tighten the lock nut at specified torque while turning wheel hub and brake drum assembly **10** several times.
- Next, slacken off the lock nut fully until a clearance is obtained between lock nut **7** and lock washer **8**.



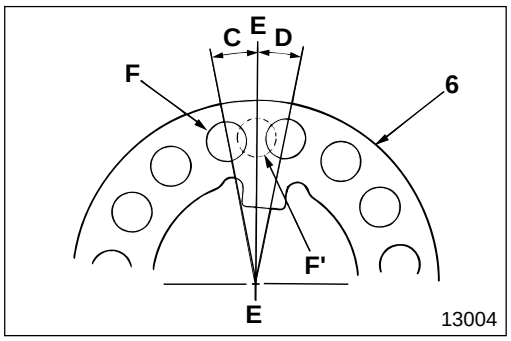
- Return outer bearing **9** toward lock nut **7** by hitting illustrated part **A**, while turning wheel hub and brake drum assembly **10** again.
  B : Copper-headed mallet



★ • After retightening lock nut **7** at specified torque, slacken it off by 30° (one twelfth of a turn).
(★ : If there is any deviation found when you measure the tangential force, carried out following the procedure on 🕮 P26-19, repeat the work.)

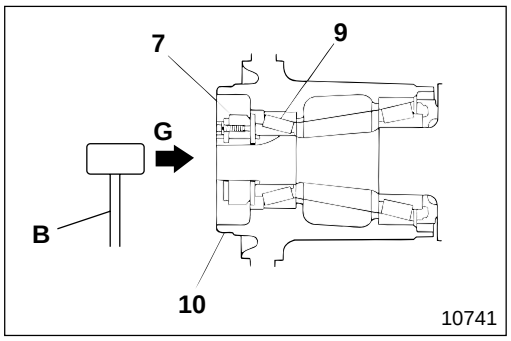


- Install lock plate **6**.
- Make sure that the bolt mounting holes of lock plate **6** and lock nut **7** align.
- Tighten mounting bolts **5** at specified torque.



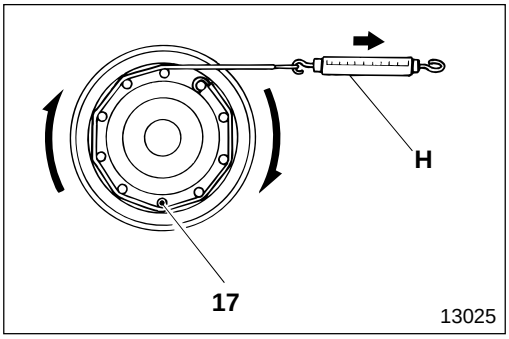
- If the mounting holes of lock plate **6** and lock nut **7** do not align, align as follows:

Hole position of lock nut	How to align hole of lock plate
Within range **C**	Loosen lock nuts to align holes
Within range **D**	Turn over lock plate and loosen lock nut to align holes
On **E**–**E** line	Turn over the lock plate to align the holes (Lock nut hole position changes from **F'** to **F**)



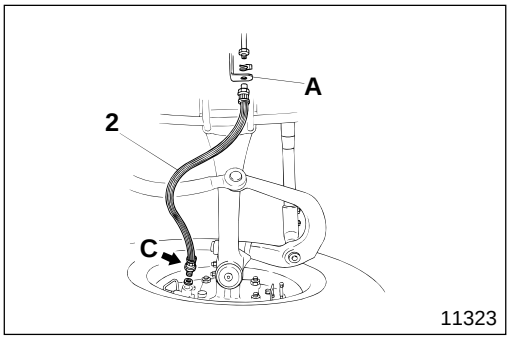
- To slide outer bearing **9** towards lock nut **7**, hit end **G** two or three times with a copper-headed mallet, while turning wheel hub and brake drum assembly **10**.
B : Copper-headed mallet

- Once again, hit one end of the knuckle two or three times with a soft-faced mallet while turning the hub and drum assembly so that the outer bearing fits tightly to the lock nut.



[Measurement]
- Fasten spring balance **H** to hub bolt **17** and measure the tangential force.
- If the measured tangential force is the standard value, the starting torque conforms to the standard value.
- Make sure that the starting torque is smaller than the tangential force.
- If the tangential force deviates from the specified value, adjust the starting torque again.
- If the measured value deviates from the specified value, redo the procedure from the item marked ★. 📖 P26-18
- If any fault is found after adjustment, replace outer bearings **9**, **14** and inner bearings **13**, **26**.

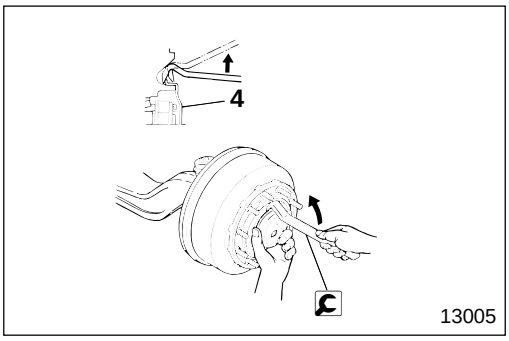
NOTE
- **Measure the starting torque when oil seal 12 has been installed.**
- **Make sure that the brake lining and brake drum 16 do not drag before measurement.**



2 Removal and installation of brake hose

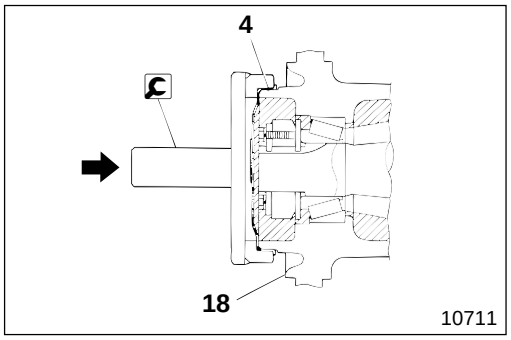
Remove the brake hose from frame side **A** first, then disconnect from wheel brake side **B**. For installation, connect the hose in a reverse order.

CAUTION ⚠
Make sure that brake hose 2 is not twisted when you install it.



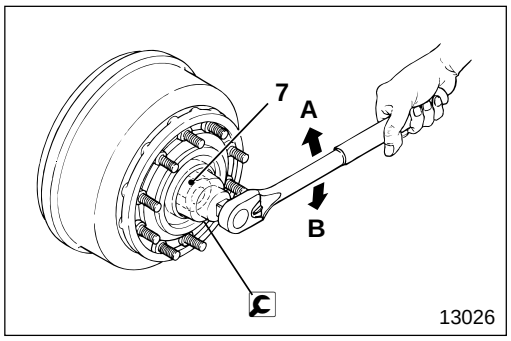
4 Wheel hub cap

[Removal]



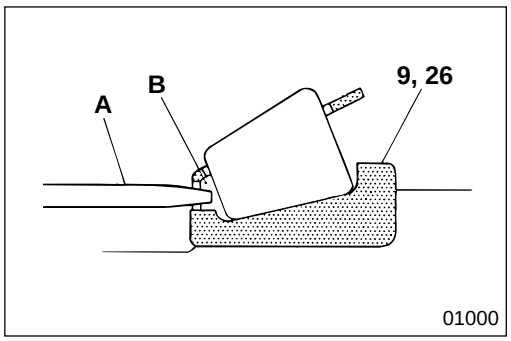
[nstallation]
Pack wheel hub cap **4** with grease, apply sealant to contact surfaces of wheel hub **18**, and press-fit it.

CAUTION
Do not use a hammer, etc. when you install wheel hub cap 4, or you might deform the mating surface, destroying watertightness.



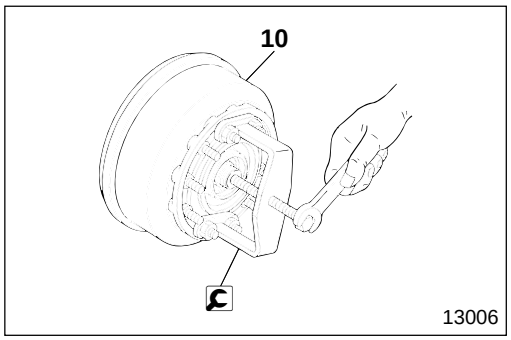
7 **Removal and installation of lock nut**

See adjustment of wheel hub bearing starting torque. P26-17
A : Removal
B : Installation



9 **26** **Packing grease in outer bearing inner race and inner bearing inner race**

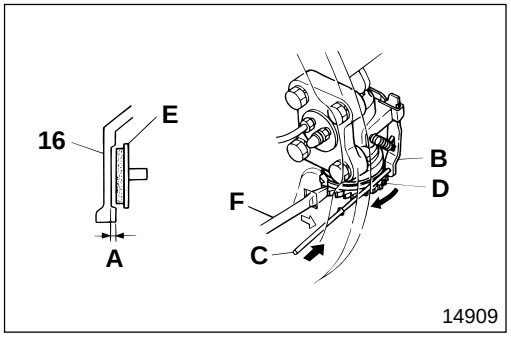
A : Grease pump nozzle
B : Between rollers



10 **Wheel hub and brake assembly**

[Removal]

CAUTION
Make sure you remove wheel hub and brake drum assembly 10 in a straight line to prevent damage to oil seal 12.



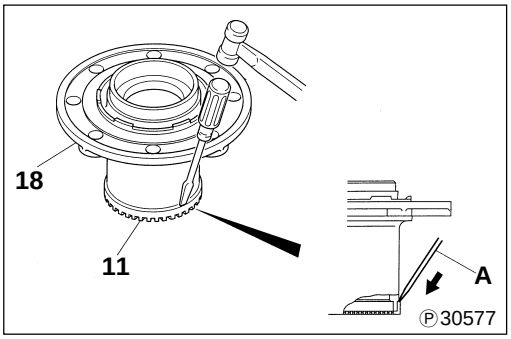
If wheel hub and brake drum assembly **10** cannot be removed because of stepped wear **A** in brake drum **16**, carry out the following:

- Remove the packing plate cover.
- Lift lever **B**.
  C : Wire approximately ø5 mm {0.020 in.}
- Turn adjuster **D** in the opposite direction to the arrow on the packing plate, and expand the clearance between brake drum **16** and brake shoe assembly **E**.
  F : Screwdriver
- Remove wheel hub and brake drum assembly **10**.

CAUTION

If brake drum 16 is faulty, correct it. Gr 35A

[Installation]
After installing wheel hub and brake drum assembly **10**, adjust the brake shoe clearance.
Gr 35A

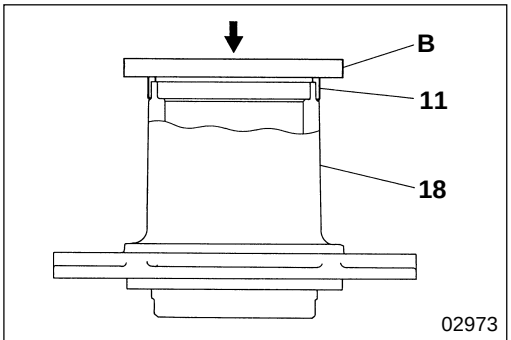


11 Rotor

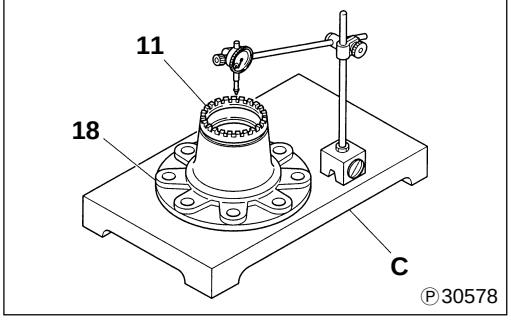
[Removal]
Strike the outer edge of rotor **11** evenly with flat-tip screwdriver **A** to remove the rotor from the wheel hub.

CAUTION

Be careful not to damage wheel hub 18.

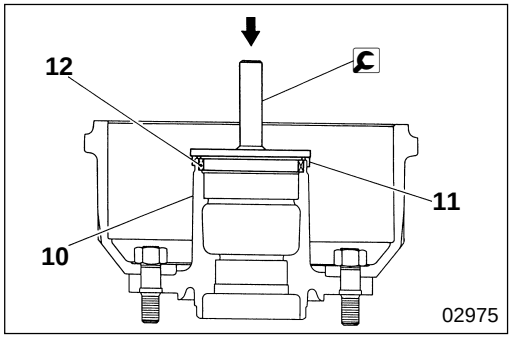


[Installation]
Heat rotor **11** to approximately 150°C {302°F}. Press the rotor evenly with iron plate **B** to press-fit the rotor to wheel hub **18**. Make sure there is no space between the rotor and wheel hub.



[Inspection]

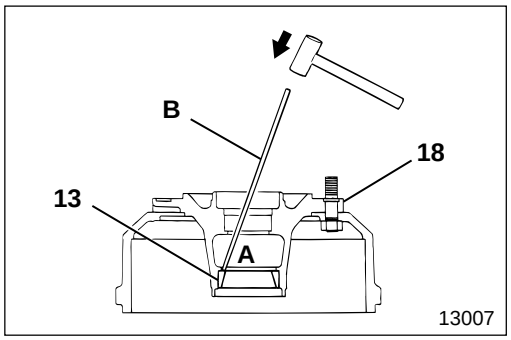
- If the amount of wobbling exceeds the standard value, repeat the assembly procedure from the beginning.
- If the amount of wobbling exceeds the standard value after reassembly, replace defective parts.
  C : Base



12 Installation of oil seal

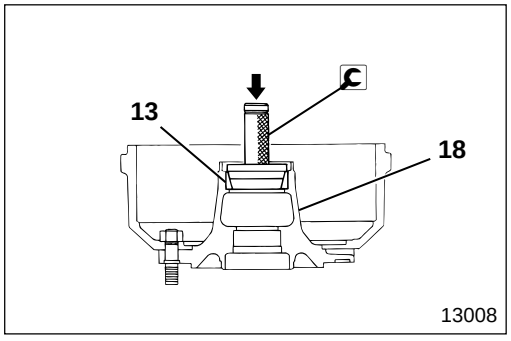
CAUTION

When hub and brake drum assembly 10 is removed for a service operation and if rotor 11 is still mounted on the wheel hub, use 0 ABS oil seal installer to press-fit oil seal 12.

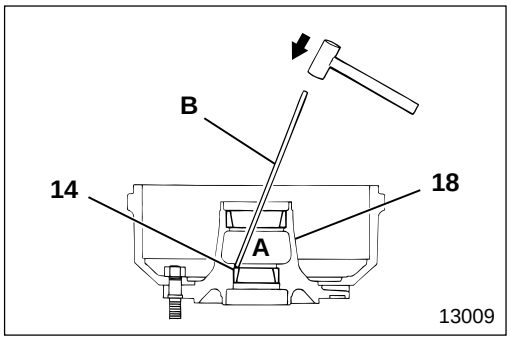


13 Inner bearing outer race

[Removal]
Drive out inner bearing outer race **13** evenly from two indented parts **A** in wheel hub **18**.
B : Pin-punch

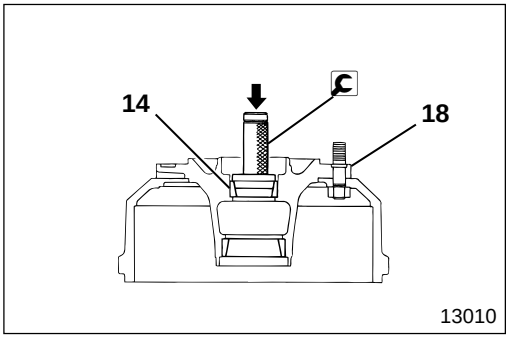


[Installation]

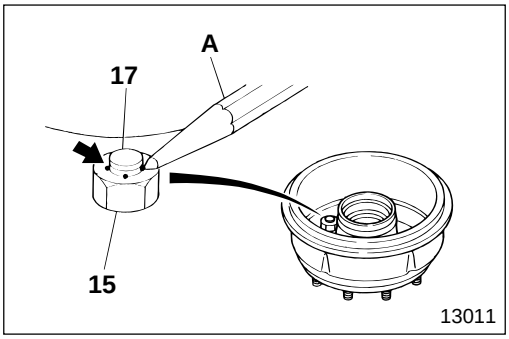


14 Outer bearing outer race

[Removal]
Drive out outer bearing outer race **14** evenly from two indented parts **A** in wheel hub **18**.
B : Pin-punch

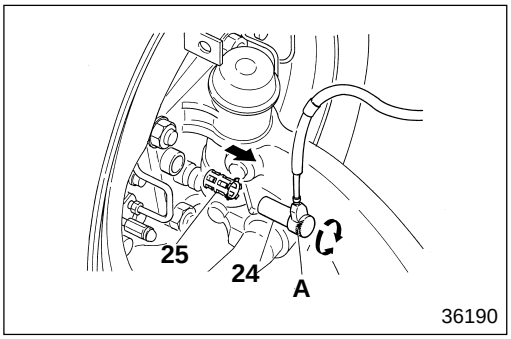


[Installation]



15 **17** **Installation of nut and hub bolts**

Tighten nut **15** at specified torque, then caulk hub bolt **17** evenly at four points.
A : Punch

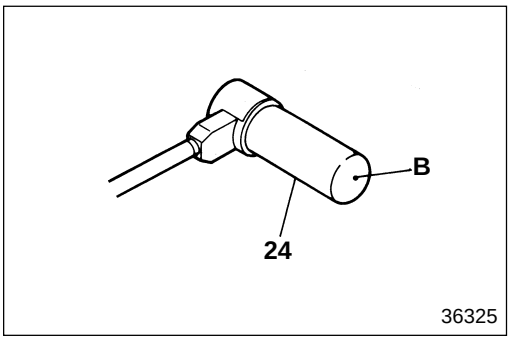


24 **Wheel speed sensor**

[Removal]
Hold shaded section **A** of wheel speed sensor **24** with pliers, and remove the sensor by twisting it slightly in left and right directions.

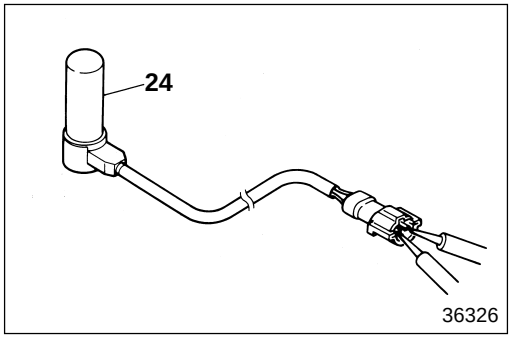
CAUTION

- **When holding wheel speed sensor 24 with pliers, do not grip any section other than shaded area A in the diagram.**
- **When removing wheel speed sensor 24, do not apply force on the sensor, such as by hitting with a hammer, prying with a screwdriver or pulling the harness, since these actions can result in wire breakage.**
- **If wheel speed sensor 24 dismounts easily, replace spring spacer 25.**

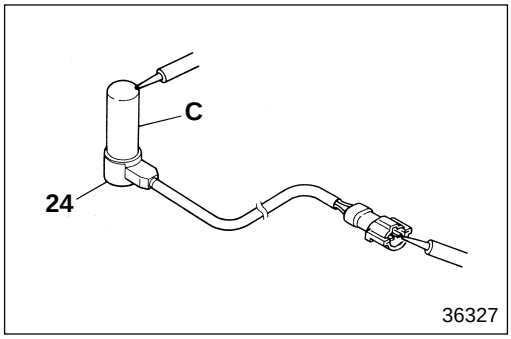


[Inspection]

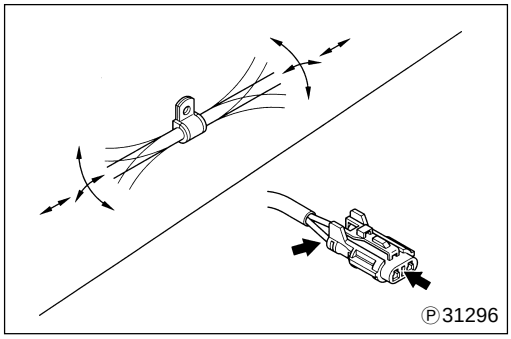
- Since pole piece section **B** is magnetized by the magnet inside wheel speed sensor **24**, it attracts metals. Do not allow the pole piece to collect metallic objects.



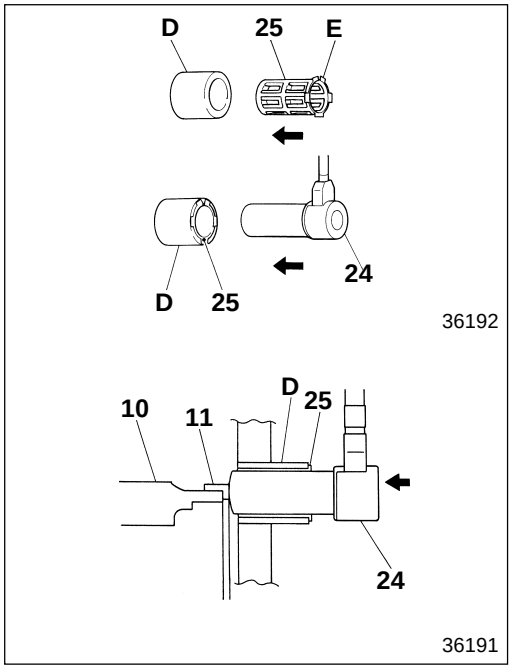
- Measure the resistance between the terminals of wheel speed sensor **24**.
  If the measured value deviates from the standard value, replace the wheel speed sensor.



- Measure the insulation resistance between body **C** of wheel speed sensor **24** and each terminal.
  If the measured values deviate from the standard value, replace the wheel speed sensor.



- To check for broken wires, remove the harness clamp section from the vehicle. Bend and extend the harness to check if there is any broken wire in the harness. Also, inspect the connector for proper contact.
  If a defect is found, replace wheel speed sensor **24**.

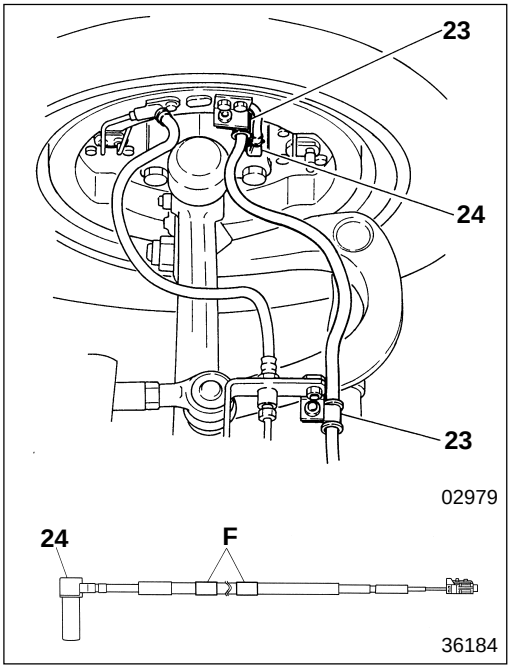


[Installation]

- Insert spring spacer **25** into holder section **D** of the knuckle, and press until stopper section **E** contacts the holder.
- Insert wheel speed sensor **24**, and press until it contacts rotor **11**.
- Rotate hub and brake drum assembly **10** slowly for two or three turns (2 seconds per turn) to make sure it rotates smoothly.

CAUTION⚠

When installing wheel speed sensor 24, do not apply force on the sensor, such as by hitting with a hammer, prying with a screwdriver or pulling the harness, since these actions can result in wire breakage.



- Secure white tape section **F** of the harness of wheel speed sensor **24** in place using clip **23** on the wheel brake side and clip **23** on the frame side.

CAUTION⚠

Be sure to clamp the harness of wheel speed sensor 24 at two white tape sections F. Make sure the harness does not interfere with other parts and there is no twist or slack in the harness.

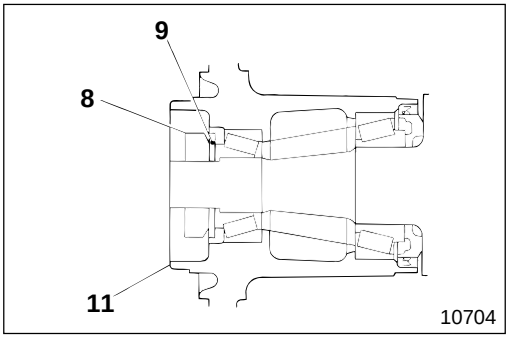
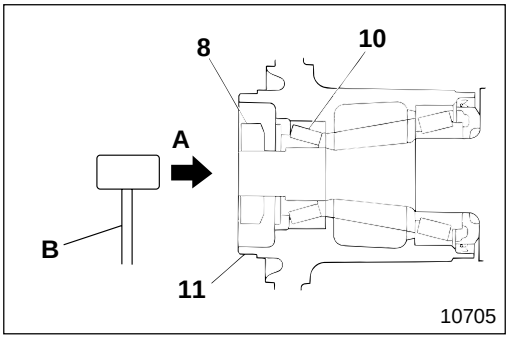
◆ Service procedure



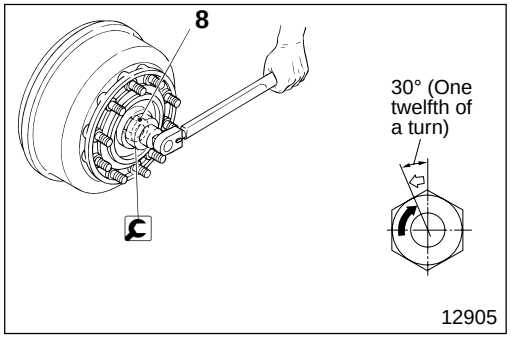
● Starting torque of wheel hub drum

[Adjustment]

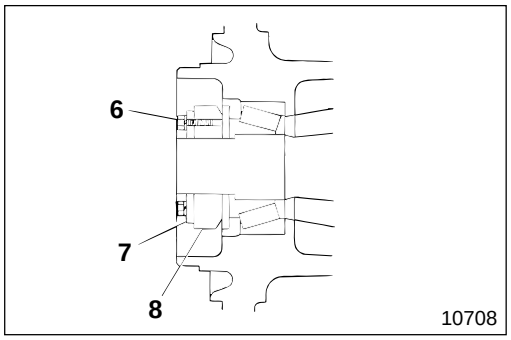
- Install lock washer **9** and lock nut **8**, then tighten the lock nut at specified torque while turning wheel hub and brake drum assembly **11** several times.
- Next, slacken off the lock nut fully until a clearance is obtained between lock nut **8** and lock washer **9**.



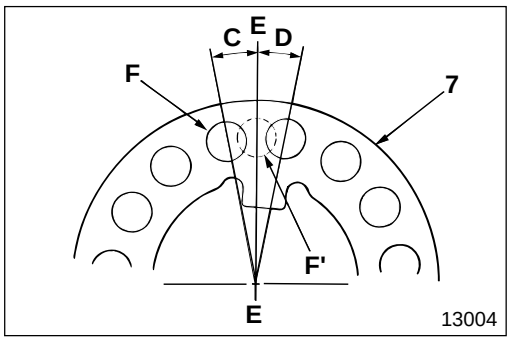
- Return outer bearing **10** toward lock nut **8** by hitting illustrated part **A**, while turning wheel hub and brake drum assembly **11** again.
  B : Copper-headed mallet



★ • After retightening lock nut **8** at specified torque, slacken it off by 30° (one twelfth of a turn).
(★ : If there is any deviation found when you measure the tangential force, carried out following the procedure on 🕮 P26-31, repeat the work.)

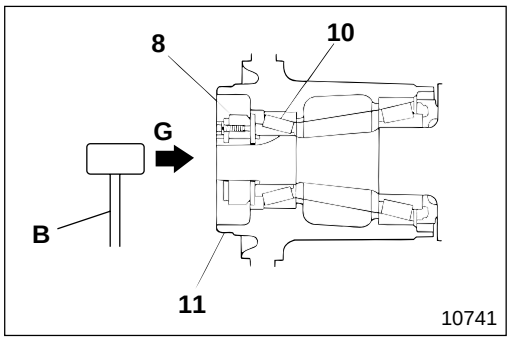


- Install lock plate **7**.
- Make sure that the bolt mounting holes of lock plate **7** and lock nut **8** align.
- Tighten mounting bolts **6** at specified torque.



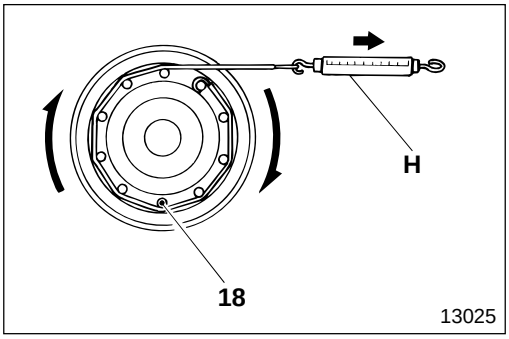
- If the mounting holes of lock plate **7** and lock nut **8** do not align, align as follows:

Hole position of lock nut	How to align hole of lock plate
Within range **C**	Loosen lock nuts to align holes
Within range **D**	Turn over lock plate and loosen lock nut to align holes
On **E**–**E** line	Turn over the lock plate to align the holes (Lock nut hole position changes from **F'** to **F**)



- To slide outer bearing **10** towards lock nut **8**, hit end **G** two or three times with a copper-headed mallet, while turning wheel hub and brake drum assembly **11**.
B : Copper-headed mallet

- Once again, hit one end of the knuckle two or three times with a soft-faced mallet while turning the hub and drum assembly so that the outer bearing fits tightly to the lock nut.

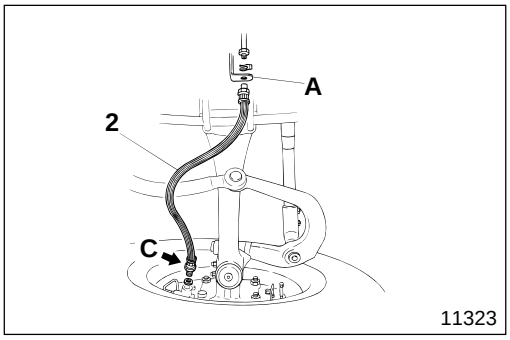


[Measurement]

- Fasten spring balance **H** to hub bolt **18** and measure the tangential force.
- If the measured tangential force is the standard value, the starting torque conforms to the standard value.
- Make sure that the starting torque is smaller than the tangential force.
- If the tangential force deviates from the specified value, adjust the starting torque again.
- If the measured value deviates from the specified value, redo the procedure from the item marked ★. P26-30
- If any fault is found after adjustment, replace outer bearings **10**, **15** and inner bearings **14**, **27**.

NOTE

- **Measure the starting torque when oil seal 13 has been installed.**
- **Make sure that the brake lining and brake drum 17 do not drag before measurement.**



2 Removal and installation of brake hose

First remove brake hose **2** from bracket **A** or connector **B** (on the frame), then remove the brake hose from wheel brake **C** or front brake chamber **D**. For installation, follow this procedure in reverse.

CAUTION ⚠

Make sure that brake hose 2 is not twisted when you install it.

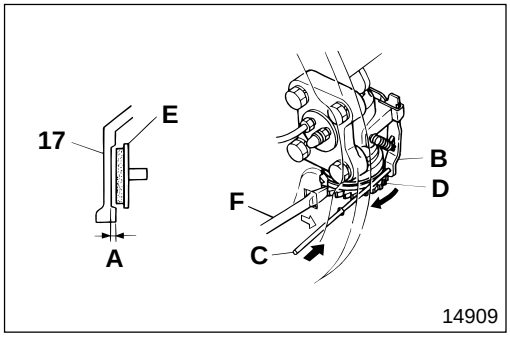
CAUTION⚠

Make sure you remove wheel hub and brake drum assembly 11 in a straight line to prevent damage to oil seal 13.



If wheel hub and brake drum assembly **11** cannot be removed because of stepped wear **A** in brake drum **17**, carry out the following:

- Remove the backing plate cover.
- Lift lever **B**.
  C : Wire approximately ø5 mm {0.020 in.}
- Turn adjuster **D** in the opposite direction to the arrow on the packing plate, and expand the clearance between brake drum **17** and brake shoe assembly **E**.
  F : Screwdriver
- Remove wheel hub and brake drum assembly **11**.

CAUTION

If brake drum 17 is faulty, correct it. Gr 35A

[Installation]
After installing wheel hub and brake drum assembly **11**, adjust the brake shoe clearance.

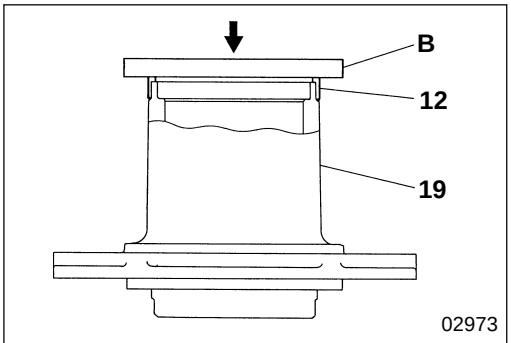
12 Rotor

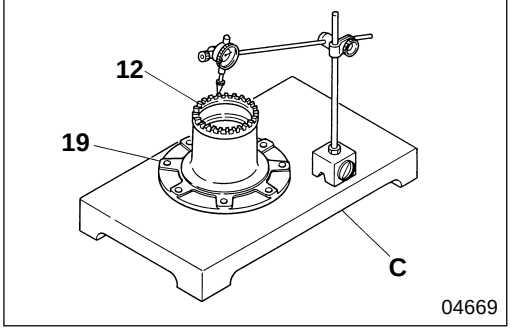
[Removal]
Strike the outer edge of rotor **12** evenly with flat-tip screwdriver **A** to remove the rotor from the wheel hub.

CAUTION

Be careful not to damage wheel hub 19.



[Installation]
Heat rotor **12** to approximately 150°C {302°F}. Press the rotor evenly with iron plate **B** to press-fit the rotor to wheel hub **19**. Make sure there is no space between the rotor and wheel hub.



[Inspection]

- If the amount of wobbling exceeds the standard value, repeat the assembly procedure from the beginning.
- If the amount of wobbling exceeds the standard value after reassembly, replace defective parts.

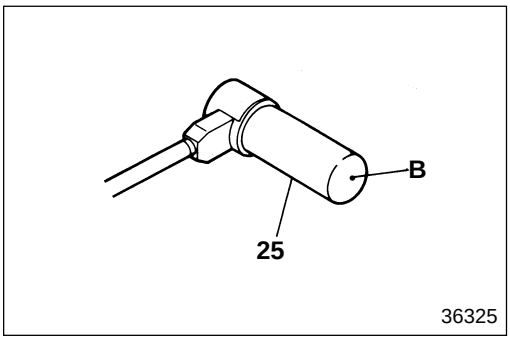
25 **Wheel speed sensor**

[Removal]
Hold shaded section **A** of wheel speed sensor **25** with pliers, and remove the sensor by twisting it slightly in left and right directions.

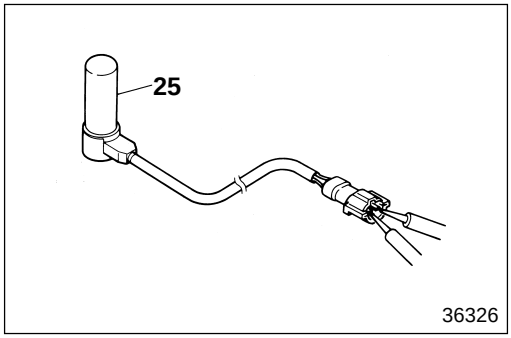
CAUTION

- **When holding wheel speed sensor 25 with pliers, do not grip any section other than shaded area A in the diagram.**
- **When removing wheel speed sensor 25, do not apply force on the sensor, such as by hitting with a hammer, prying with a screwdriver or pulling the harness, since these actions can result in wire breakage.**
- **If wheel speed sensor 25 dismounts easily, replace spring spacer 26.**

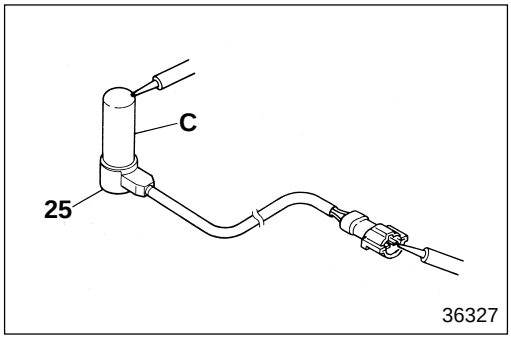


[Inspection]

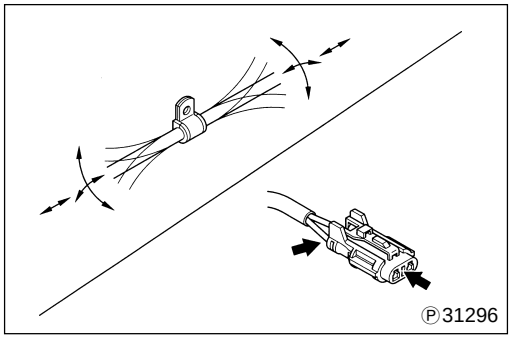
- Since pole piece section **B** is magnetized by the magnet inside wheel speed sensor **25**, it attracts metals. Do not allow the pole piece to collect metallic objects.



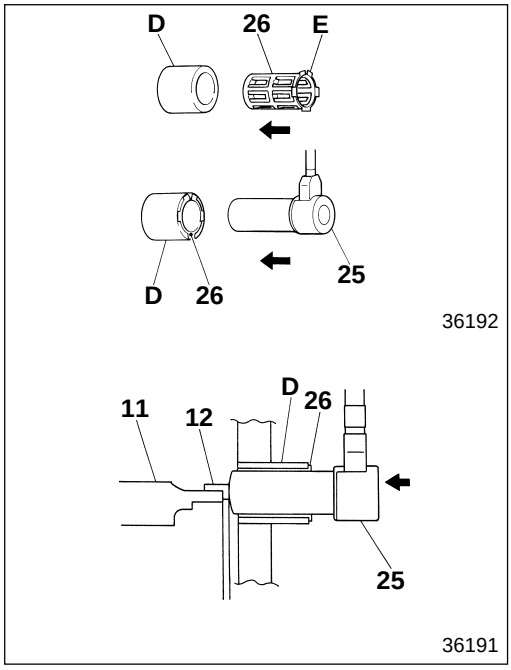
- Measure the resistance between the terminals of wheel speed sensor **25**.
  If the measured value deviates from the standard value, replace the wheel speed sensor.



- Measure the insulation resistance between body **C** of wheel speed sensor **25** and each terminal.
  If the measured values deviate from the standard value, replace the wheel speed sensor.



- To check for broken wires, remove the harness clamp section from the vehicle. Bend and extend the harness to check if there is any broken wire in the harness. Also, inspect the connector for proper contact.
  If a defect is found, replace wheel speed sensor **25**.

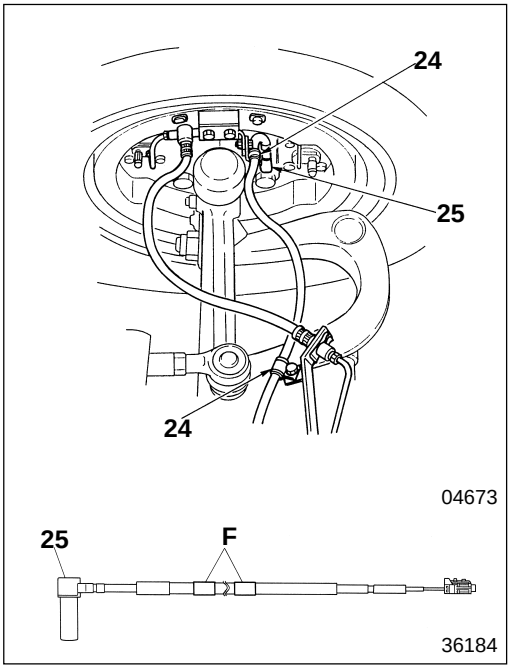


[Installation]

- Insert spring spacer **26** into holder section **D** of the knuckle, and press until stopper section **E** contacts the holder.
- Insert wheel speed sensor **25**, and press until it contacts rotor **12**.
- Rotate hub and brake drum assembly **11** slowly for two or three turns (2 seconds per turn) to make sure it rotates smoothly.

CAUTION⚠

When installing wheel speed sensor 25, do not apply force on the sensor, such as by hitting with a hammer, prying with a screwdriver or pulling the harness, since these actions can result in wire breakage.



- Secure white tape section **F** of the harness of wheel speed sensor **25** in place using clip **24** on the wheel brake side and clip **24** on the frame side.

CAUTION⚠

Be sure to clamp the harness of wheel speed sensor 25 at two white tape sections F. Make sure the harness does not interfere with other parts and there is no twist or slack in the harness.

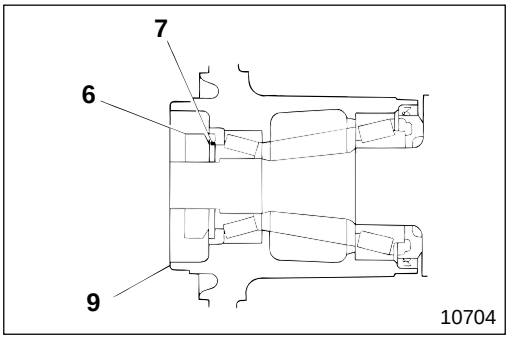
◆ Service procedure

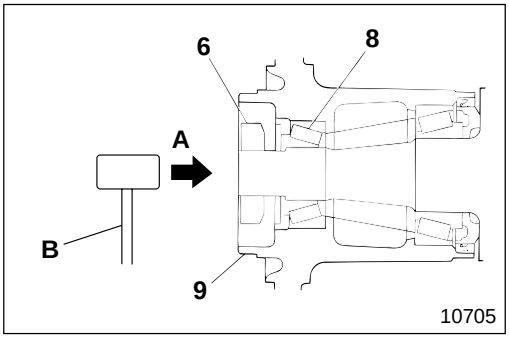


10704

● Starting torque of wheel hub drum

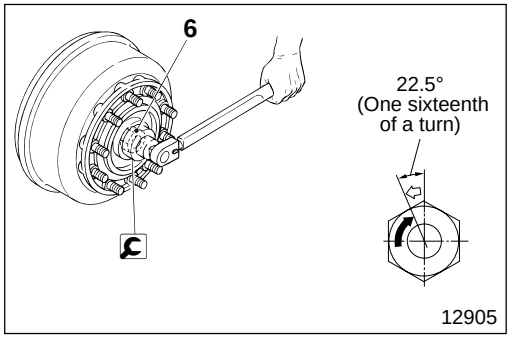
[Adjustment]

- Install lock washer **7** and lock nut **6**, then tighten the lock nut at specified torque while turning wheel hub and brake drum assembly **9** several times.
- Next, slacken off the lock nut fully until a clearance is obtained between lock nut **6** and lock washer **7**.

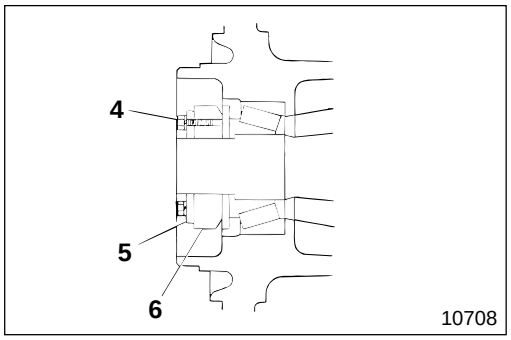


10705

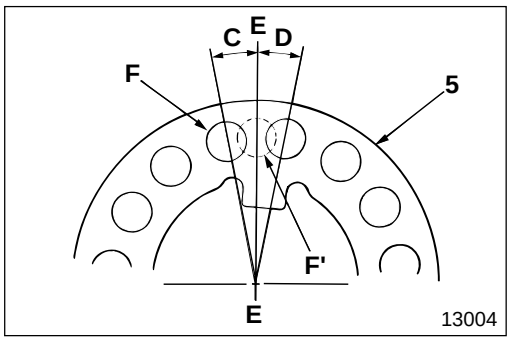
- Return outer bearing **8** toward lock nut **6** by hitting illustrated part **A**, while turning wheel hub and brake drum assembly **9** again.
  B : Copper-headed mallet



★ • After retightening lock nut **6** at specified torque, slacken it off by 22.5° (one sixteenth of a turn).
(★ : If there is any deviation found when you measure the tangential force, carried out following the procedure on 📖 P26-43, repeat the work.)

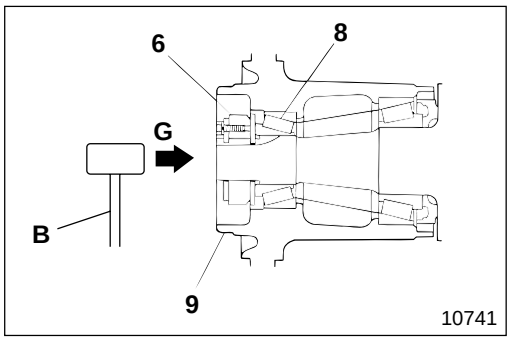


- Install lock plate **5**.
- Make sure that the bolt mounting holes of lock plate **5** and lock nut **6** align.
- Tighten mounting bolts **4** at specified torque.



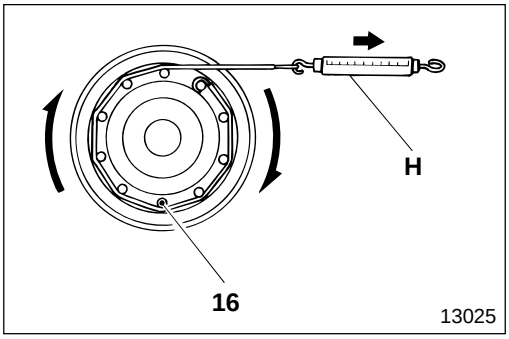
- If the mounting holes of lock plate **5** and lock nut **6** do not align, align as follows:

Hole position of lock nut	How to align hole of lock plate
Within range **C**	Loosen lock nuts to align holes
Within range **D**	Turn over lock plate and loosen lock nut to align holes
On **E**–**E** line	Turn over the lock plate to align the holes (Lock nut hole position changes from **F'** to **F**)



- To slide outer bearing **8** towards lock nut **6**, hit end **G** two or three times with a copper-headed mallet, while turning wheel hub and brake drum assembly **9**.
B : Copper-headed mallet

- Once again, hit one end of the knuckle two or three times with a soft-faced mallet while turning the hub and drum assembly so that the outer bearing fits tightly to the lock nut.

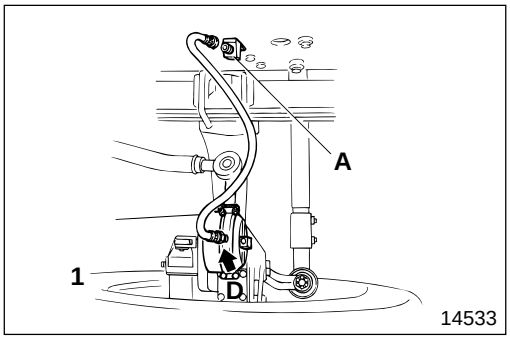


[Measurement]

- Fasten spring balance **H** to hub bolt **16** and measure the tangential force.
- If the measured tangential force is the standard value, the starting torque conforms to the standard value.
- Make sure that the starting torque is smaller than the tangential force.
- If the tangential force deviates from the specified value, adjust the starting torque again.
- If the measured value deviates from the specified value, redo the procedure from the item marked ★. P26-42
- If any fault is found after adjustment, replace outer bearings **8**, **13** and inner bearings **12**, **26**.

NOTE

- **Measure the starting torque when oil seal 11 has been installed.**
- **Make sure that the brake lining and brake drum 15 do not drag before measurement.**



1 Removal and installation of brake hose

First remove brake hose **1** from bracket **A** or connector **B** (on the frame), then remove the brake hose from wheel brake **C** or front brake chamber **D**. For installation, follow this procedure in reverse.

[Installation]

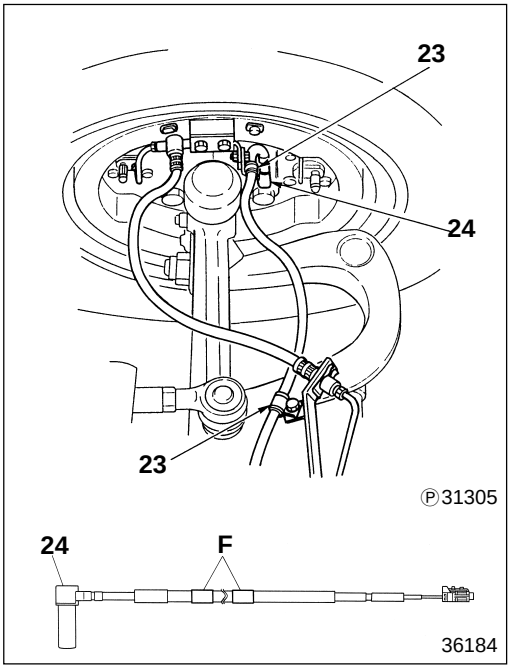
- Insert spring spacer **25** into holder section **D** of the knuckle, and press until stopper section **E** contacts the holder.
- Insert wheel speed sensor **24**, and press until it contacts rotor **10**.
- Rotate hub and brake drum assembly **9** slowly for two or three turns (2 seconds per turn) to make sure it rotates smoothly.

CAUTION⚠

When installing wheel speed sensor 24, do not apply force on the sensor, such as by hitting with a hammer, prying with a screwdriver or pulling the harness, since these actions can result in wire breakage.



- Secure white tape section **F** of the harness of wheel speed sensor **24** in place using clip **23** on the wheel brake side and clip **23** on the frame side.

CAUTION⚠

Be sure to clamp the harness of wheel speed sensor 24 at two white tape sections F. Make sure the harness does not interfere with other parts and there is no twist or slack in the harness.

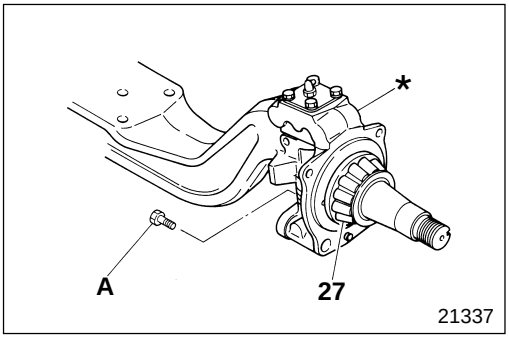
- Secure white tape section **F** of the harness of wheel speed sensor **25** in place using clip **24** on the wheel brake side and clip **24** on the frame side.

CAUTION⚠

Be sure to clamp the harness of wheel speed sensor 25 at two white tape sections F. Make sure the harness does not interfere with other parts and there is no twist or slack in the harness.



27 **Inner bearing inner race**

[Removal]

Turn the knuckle stopper bolt on the knuckle *, or screw two bolts **A** (M14 x 1.5 mm) evenly into the screw plug mounting holes to remove inner bearing inner race **27**.

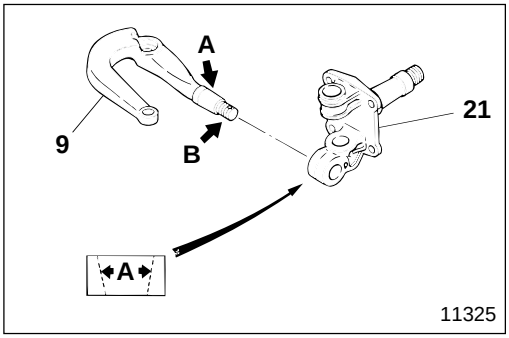
● Work after assembly

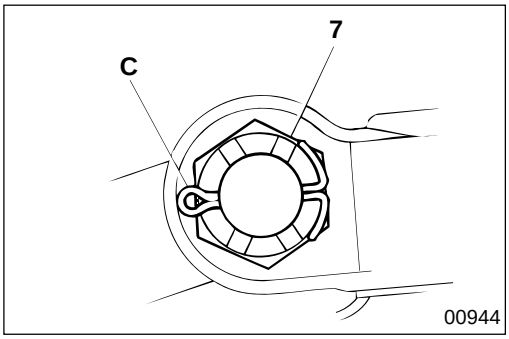
Supply grease via grease nipple **20** of knuckle **21**. Supply grease until it overflows from the dust plugs of upper cap **12**, thrust washer **16**, and the press side of ball bearing **17**.



9 **21** **Installation of knuckle arm and knuckle**

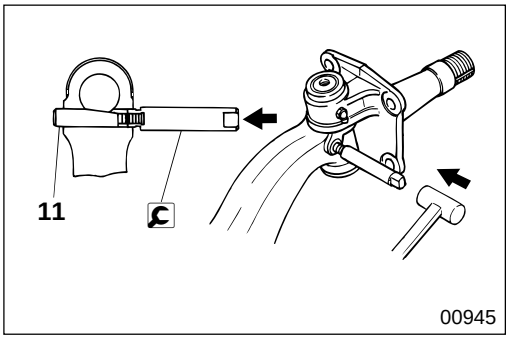
(1) Reassembly of existing knuckle arm 9 and/or knuckle 21

- Evenly polish taper surfaces **A** of knuckle arm **9** and knuckle **21** using emery paper (120 grit or finer), until abrasion traces left by the emery paper are only just visible. For new parts, polishing is not required.
- Clean taper surfaces **A** of knuckle arm **9** and knuckle **21** and thread area **B** of the knuckle arm. (Use a cleaning solvent for acetone color checking or other solvent.)
- Install knuckle arm **9** after applying grease to thread area **B**. (Do not grease the taper surfaces of the knuckle arm and the knuckle.)
- Tighten new nut **7** at specified torque. Without loosening the nut, insert split pin **C** into the pin hole to lock the nut.

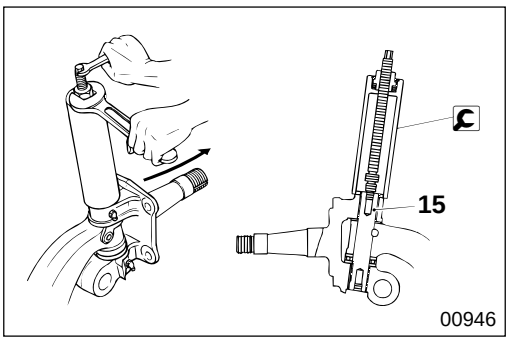


(2) Installation of new knuckle arm 9 and knuckle 21

- Clean taper surfaces **A**, or thread area **B**, of knuckle arm **9** and knuckle **21**, and install them without greasing.
- Tighten new nut **7** at specified torque. Without loosening the nut, insert split pin **C** into the pin hole to lock the nut.

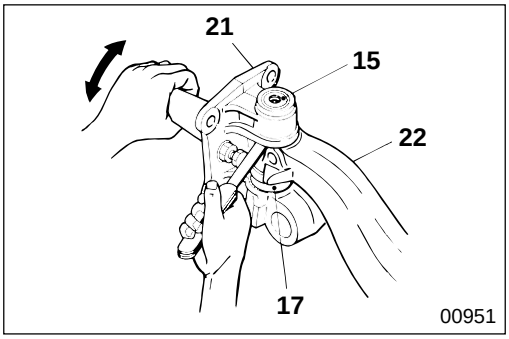


11 **Removal of set bolt**



15 **Removal of kingpin**

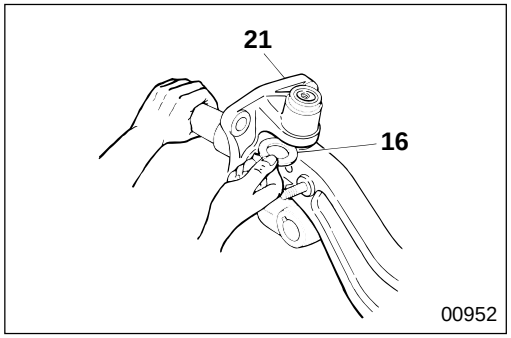
- Remove the kingpin cap. Screw the bolt of kingpin puller into the threads of kingpin **15**, and remove the kingpin.



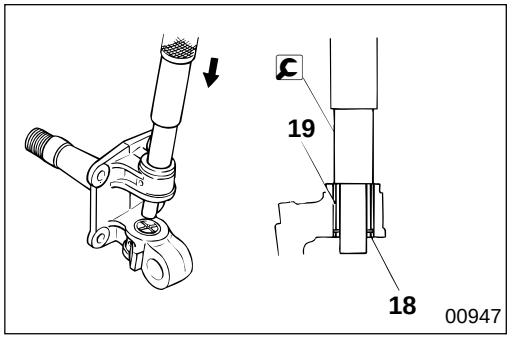
16 **21** **22** **Thrust washer, knuckle, and front axle**

[Inspection]

- Assemble kingpin **15** and bearing **17** temporarily, and turn knuckle **21** a couple of times to smooth its operation.
- Measure the clearance between the upper surface of front axle **22** and the lower part of knuckle **21**.
- If the measured value is higher than the limit, adjust with thrust washer **16**.

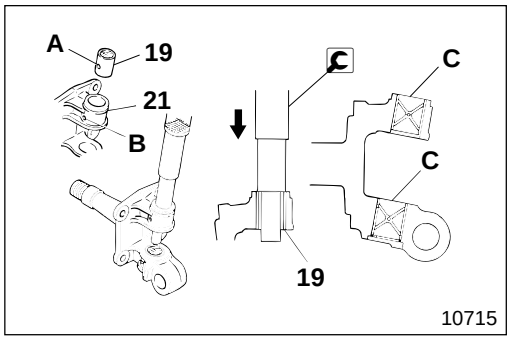


[Adjustment]
- Adjusting thrust washers **16** are available in the following sizes: 2.1 to 2.8 mm {0.083 to 0.11 in.} (eight thicknesses in 0.1 mm {0.0039 in.} increments)
- Be sure to minimize the clearance by selecting appropriate thrust washer **16**.
- Make sure that knuckle **21** moves smoothly after assembly.

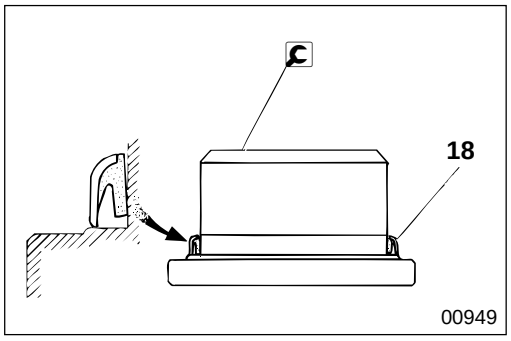


18 **19** **Oil seal and bushing**

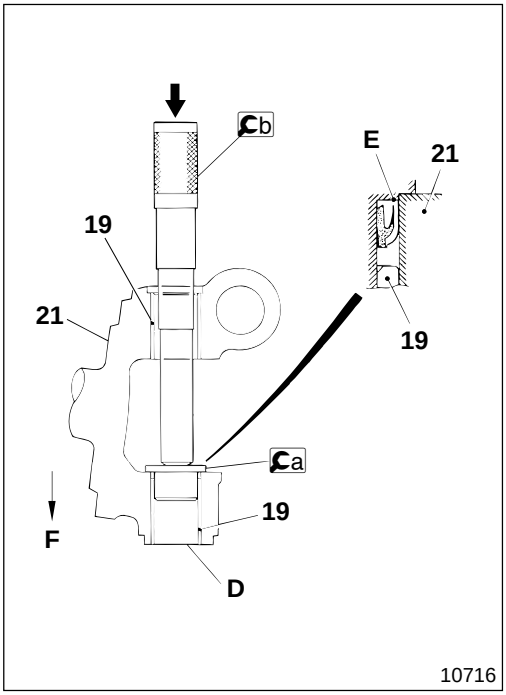
[Removal]



[Installation]
- Press bushing **19** in, with its oil hole **A** aligned to oil hole **B** of knuckle **21**, until end **C** is flush with the knuckle end.



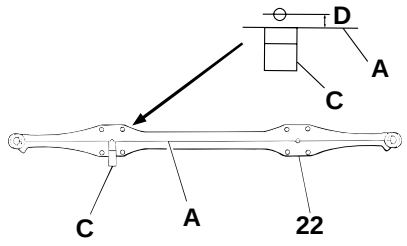
- Apply grease to the lip area of oil seal **18**, and position the oil seal on oil seal installer.



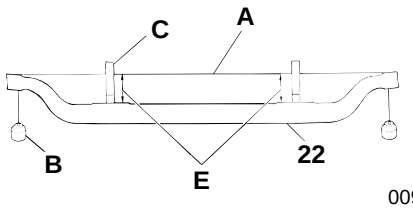
- Next, install a oil seal installer on knuckle **21** in the direction as illustrated.
- Pass b kingpin bushing remover through the kingpin hole and position it on a oil seal installer.
- Hit the head of b kingpin bushing remover until a oil seal installer makes contact with the knuckle.
- Make sure that end **D** of bushing **19** makes contact with knuckle **21** on the same level.
- Make sure that oil seal end **E** does not protrude from knuckle **21**.

F : Upper side of vehicle

< Longitudinal direction >



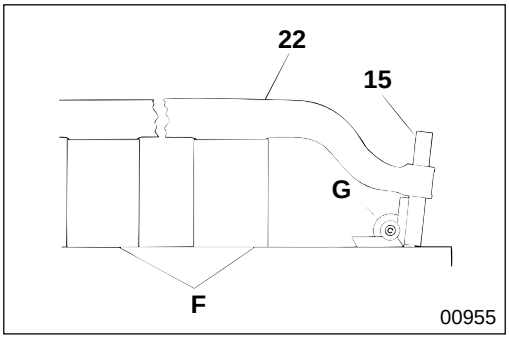
< Vertical direction >



22 Inspection of front axle

(1) Measurement of bend in front axle 22 in longitudinal and vertical directions

- Pass a piece of thread **A** through the kingpin hole of front axle **22** and hang weights **B** on both ends.
- Use square **C** to find the degree of bend in both the longitudinal direction **D** and the vertical direction **E**.
- If the measured value is higher than the limit, replace front axle **22**.



(2) Measurement of kingpin inclination angle

Mount kingpin **15** in front axle **22** as illustrated, and measure the kingpin inclination angle. If the measured value is higher than the limit, replace the front axle.

G : Bevel square
